Ger., 283,340, Mar. 13, 1913. F. & M. LAUTENSCHLÄGER G. M. B. H. Disinfecting by means of HCHO in closed chambers. The HCHO is mixed with the vapor of acetone, MeOH , or like liquid, which boils under 100° at atm. pressure and which has a greater d. than air, and this mixt. is conducted through the disinfecting

app., expelling from the chamber and from the materials contained therein for treatment, the specifically lighter air. *E. g.*, 15 parts formalin vapor are mixed with 100 parts acetone vapor so that in the app. a mixt. of vapors containing about 2% HCHO is brought into action. A suitable construction is specified.

Ger., 283,475, Jan. 10, 1913. G. ERLWEIN. Process of removing H_2O_2 from sterilized water. The removal of the excess of H_2O_2 used in sterilization is necessary on account of the taste, and also the deleterious action as a constituent of potable water. This is effected by treatment with MnO_2 , or its hydrate, Mn_2O_4 or its hydrates, or with mixts. of these. A sand or gravel filter containing these Mn-compds. is prepared, as in the removal of Mn-compds. from H_2O , and the H_2O containing H_2O_2 is passed through this filter at a suitable rate of flow. As carrier for the active mass, neutral or artificial zeolites, or their Mn compds., can be employed. Or, the specified Mn-compds. can be used in powder or granular form as the filter mass. Or, the specified Mn-compds. may be added to the H_2O and left in contact therewith for some time. Shaking or stirring hastens the action. If the filter is exhausted, it can be regenerated by permanganate or chloride of lime soln., when it is ready for use.

15. SOILS AND FERTILIZERS.

R. O. E. DAVIS.

Progress in the field of agricultural chemistry in 1914. PAUL EHRENBURG. Göttingen. *Chem. Ztg.* 39, 453-5, 470-2 (1915).—A review, with bibliography.

J. H. MOORE.

Ideas concerning agricultural analysis. C. GUÉDROITZ. *Russ. J. Exp. Landw.* 16, 83-94 (1915).—G. discusses loss by calcination in soils, the total mineral substances of soil which are sol. in water, and the decomp. of soil by treatment with HF in the presence of HCl.

W. H. FRY.

Potassium from the soil. CYRIL G. HOPKINS AND J. P. AUMER. Illinois Agr. Expt. Sta., *Bull.* 182, 10 pp. (1915).—(1) "K can be liberated as needed from the inexhaustible supply naturally contained in the normal soils of Illinois. (2) The amt. of K taken up from ordinary Illinois soil by clover is from 2 to 3 times the amt. required for plant growth. The excess probably is merely tolerated, as is Na and Si, both of which are present in the soil soln. and are taken up by plants in considerable amts., although neither is essential for plant growth."

B. E. B.

Effects of variations in moisture content on certain properties of a soil and on the growth of wheat. F. S. HARRIS. New York Cornell Sta., *Bull.* 352, 805-68 (1914).—A report on greenhouse and laboratory expts. with wheat plants grown in pots containing clay loam soil subjected to varying moisture and fertilizer treatments; and also on studies of certain properties of cropped and uncropped soils standing for long periods under such conditions. The cropped soil was found to be more compact than the uncropped and the vol. of the soil decreased as the moisture content increased; this was especially true when fertilizers were added. Flocculation was greater in cropped soils and was greater with a medium amt. of soil moisture than with a very great or very small amt. of moisture. Flocculation was increased by fertilizers. NO_3 content was always greater in uncropped soils and in soils to which nitrate fertilizers had been added, and was also greater in the presence of 30% moisture than where the limits were above or below this amt. No nitrates were present, practically at least, when a satd. condition was maintained. NO_3 content was always low but ran higher in the uncropped soil. NH_4 content, on the other hand, was higher in the cropped soil. The ratio of sol. salts to nitrates was higher in cropped soil. The % of N in both grain and straw was highest on the driest soil and gradually decreased as the moisture

increased up to 37 $\frac{1}{2}$ %, increasing slightly, however, as the point of satn. was approached. High N fertilization always increased the N content of the crop. The content of crude ash, Ca, Mg, K, and P₂O₅ in wheat straw grown with high moisture was lower than when a low amt. of moisture was maintained.

B. E. B.

The effect of some organic soil constituents upon nitrogen fixation by *Azotobacter*. H. S. REED AND BRUCE WILLIAMS. *Centr. Bakt. Parasitenk., II Abt.* 43, 166-76 (1915).—This paper reports a study on the effect of various organic compounds on the growth of *Azotobacter*. The purpose was to exam. the theory that the soil contains organic substances which are deleterious to plant growth and which are important factors in influencing soil fertility and especially to det. whether or not this toxicity extended to the lower plants. *Azotobacter* was chosen as a representative of the soil flora since it is of recognized importance in the maintenance of soil fertility and its growth may be accurately measured by analytical means. The compds. used were those likely to be constituents of the soil. Fixation of N by *Azotobacter* was only slightly influenced by most of the compds. investigated. A depression is noted in many cases, but it is usually the result of a relatively high concn. of the compd. used. Hydroquinone and salicylaldehyde had the most toxic action of any of the compds. studied. Esculin, quinic acid and borneol caused marked stimulation in the growth of the organism. The effects of the compds. on *Azotobacter* are not, as a rule, in accord with what has been reported of their action on the higher plants. In concs. which are fatal to certain higher plants, many compds. only slightly depressed fixation. A number of nitrogenous compds. were investigated. Such compds. as nicotine, picoline, guanidine, and skatole exhibited toxic properties commensurate to those usually ascribed to these substances. Caffeine appeared to stimulate the growth of the organism. Many of the nitrogenous substances which have been reported as beneficial to higher plants exercised a marked depression on fixation. It appears that the simpler compds. are more pronounced in this respect than are the more complex ones. It is suggested that this condition is not one of toxicity but that the combined N is utilized by *Azotobacter* in preference to that of the atmosphere. Urea, glyocoll, formamide, and allantoin were especially active in depressing fixation.

JULIAN H. LEWIS.

Influence of protozoa upon soil bacteria. T. GOODEY. *Proc. Roy. Soc. London (B)* 88, 437-56(1915); cf. *Ibid* 84, 165(1911).—Expts. on bacterial growth were made on 3 soils from Rothamsted; A had been stored since 1846 and contained no protozoa; B dated from 1870 and contained amebae and flagellates but no ciliates; C was fresh field soil. It is concluded that protozoa, added to soil, do not act as a factor limiting bacterial activity, and therefore that the ciliates, amebae and flagellates obtainable from ordinary soil under cultural conditions do not function as the limiting factor.

R. O. E. DAVIS.

Lake county soils. CYRIL G. HOPKINS, J. G. MOSIER, E. VAN ALSTINE AND F. W. GARRETT. Illinois Agr. Expt. Sta., *Soil Rept.* 9, 52 pp.(1915).—The various soil types are indicated and chem. analyses given. The amt. of limestone present is shown and results for soil acidity are given. A number of important pot and field expts., some covering a number of years, are reported on.

B. E. BROWN.

Investigations on soils and fertilizers in Hawaii. E. V. WILCOX AND W. P. KELLEY. *Hawaii Sta. Rept.* 1914, 14-16, 21, 22, 25-27; *Expt. Sta. Rec.* 32, 721(1915).—Brief summaries are given of the main results of investigations, including the effect of heating on soils (cf. C. A. 8, 976, 1479), fertilizing rice (cf. C. A. 8, 1479), the nature of the nitrogenous compds. of soil (cf. C. A. 8, 1479), effect of fertilizers on the chem. and physical properties of soils and on the fixation of fertilizing constituents by soils, and ammonification and nitrification in soils (cf. C. A. 8, 2770). Continued pot expts. with various forms of phosphate have demonstrated anew that sol. phosphates do not leach through

the soils, but remain permanently available for plant growth. Legumes used as green manure greatly increased the availability of rock phosphate. In comparative tests of various green manure plants it was found that an introduced leguminous weed known as rattlespod (*Crotalaria salsiana*) has the advantage over cultivated legumes, that the seed may be sown without any previous prepn. of the soil and of course without cultivation after seeding. On several plantations fields which had become the poorest on the whole plantation gave the largest yield during the past year as a result of plowing under humus-forming material, but without applying excessive amts. of commercial fertilizers.

Systematic scheme for experimental work with fertilizers. A. T. STUART. *Trans. Roy. Soc. Canada* [3] 8, 167-76(1914).—Because of the great number of factors influencing the use of fertilizers it is difficult to make general recommendations. The meaning of the law of minimum as applied to fertilizers is discussed and curves illustrating the law are given. By use of a solid diagram of 4 dimensions with a triangle as the base (thus forming a prism) S. is able to obtain any possible combination of the fertilizer elements N, K and P. The corners of the triangular base represent the elements and the fourth dimension represents the total quantity of all the elements applied. Systematic tests of fertilizers may be made by selecting points on the triangular diagram. Tables are given showing a plan for comparing the relative value of different forms of N, P and K in a 3 years' rotation.

R. O. E. DAVIS.

A study of vanadium and the action of some vanadates in vegetables. E. C. RAMIREZ. *Thesis, Univ. La Plata* 1914; *Anales soc. quim. Argentina* 2, No. 6, 145-6 (1914).—A general discussion on V and the principal V-bearing substances in Argentina is given. R. investigated the effect of V on plant growth. His conclusions are that this element may be absorbed and stored by plants, which may show anomalies of growth as the result of this.

B. E. BROWN.

Readily extractable phosphorus and the adequacy of phosphatic nutrition. Preliminary communication. I. JAKOUCHKINE. *Russ. J. Exp. Landw.* 16, 118-39 (1915).—Expts. show that: for materials poor in fat, especially straw, extrn. with alc. and ether does not sensibly alter the P_2O_5 content of acid exts. Direct pptn. with citric acid may be used to sep. the mineral phosphates of phytin, but more accurate results may be obtained by pptn. with magnesia mixt. in the presence of citric acid soln. by HNO_3 and detn. by the method of Neuman. Straw reflects the condition of the medium supplying P_2O_5 much more than does grain. Phytin of grain is to a great extent produced by the medium. Fertility of the soil is shown most clearly by the contents of mineral phosphates in the straw. A content of 0.07-0.10% indicates that the soil needs phosphatic manure. A content greater than 0.15% indicates a sufficiency. Mineral phosphates of vegetable organs are almost entirely sol. in water. W. H. F.

Results of some experiments with farmyard manure. R. A. BERRY. *West of Scotland Agr. Bull.* 65, 177-251(1914).—After 4 months' storage in well trodden heaps the indoor manure lost 17.5% in wt., the outdoor manure 20.6% (av. rainfall was 39.32 in.). The outdoor manure lost 28.4% of its N, the indoor only 20.4%, and while the indoor lost practically no P_2O_5 or K_2O the outdoor manure lost approx. $\frac{1}{4}$ of each constituent. Stored manure (under cover) caused a 7% better yield of potatoes and turnips than did the uncovered manure. Rotted manures were poorer in total and available N than the fresh, the losses being greater in the outdoor than in the indoor

manure. Ammoniacal N was lost to the greatest extent, the loss amounting to from 70 to 80% of that of the fresh manure, 18 % of the total N of which was in the ammoniacal form. There was a slight increase of amide and of insol. N in the rotted manure. The 2 fresh manures richest in N (those from fattening steers and from horses with peat moss as litter), were left poorer in N after rotting, while the fresh manures relatively poor in N (those from cows, pigs and horses, with straw as litter), were left slightly richer in N after rotting. The average loss of manurial constituents in the 5 manures during rotting was: Total N 2.96, total P_2O_5 12.2, and total potash 33.5%. Rotting lowered the fertilizing value of the different manures, judging by crop yields of potatoes and turnips. Gypsum and $NaHSO_4$ fixed NH_3 in the manure better than other substances and $CHCl_3$ checked fermentation best of all. In tests with fresh and rotted manure applied in fall and spring in 2 different rotation expts., it was found that fresh manure applied in drills in the spring gave the best results. The relative efficiency of the manures was found to be due to the available N. B. E. B.

Phosphatic manures and the root system of beets. V. SAZANOV. *Russ. J. Exp. Landw.* 16, 140-65(1915).—Sol. phosphoric acid of manures becomes fixed in the bed of chernozem to which it is applied and consequently no considerable displacement of phosphoric acid from one bed to another is observed. Superphosphate applied to a soil favors excessively the development of the lesser radicles of the beet to the detriment of the development of the most powerful radicle. W. H. FRY.

Cacao. Report on experiments for the year September 1, 1913, to August 31, 1914. J. DE VERTEUIL. *Bull. Dept. Agr. Trinidad and Tobago* 14, Part 3, 74-97.—Plot expts. with sheep manure, bone meal, K_2SO_4 , $(NH_4)_2SO_4$, pen manure, basic slag, bird manure, lime, mulch, Ohlendorff's cacao manure, and superphosphate, are reported. W. H. F.

Fungicide experiments, 1914. G. P. DARNELL-SMITH. *Agr. Gas. N. S. Wales* 26, 494-5(1915).—Expts. on wheat seed for prevention of infection with bunt were carried out with $CuSO_4$ solns. of varying strength and with solns. of $CuSO_4$ and lime water. Dipping wheat seed for 3 min. in 1.5% soln. of $CuSO_4$, followed by a dipping 3 min. in lime water, has, up to the present, been found the most effective "pickle" for preserving germinating capacity and preventing bunt infection. W. H. FRY.

Studies on changes in the degree of oxidation of arsenic in arsenical dipping baths. ROBERT M. CHAPIN. U. S. Dept. Agr., *Bull.* 259, 1-12(1915).—All arsenical dipping baths contain oxidizing organisms, which work slowly, and reducing organisms, which work very rapidly at times, but spasmodically. Reducing organisms exert an appreciable effect only in vats used at frequent intervals for dipping large numbers of cattle, while the ordinary vat, used once a fortnight, is likely to show only a slow, steadily progressing oxidation of the As; hence a control test of such a vat is necessary. $HCHO$ used in the proportion of 1 gal. to every 1,500 gals. of original liquid introduced into the vat is suggested as a safe and effective means for reducing oxidation to a low figure; however its use is economic rather than essential to the results obtained in dipping. E. H. INGERSOLL.

Sources of potash (MACDOWELL) 18. Fixation of atmospheric nitrogen (PRINSEN-GERLIGS) 18.

U. S., 1,145,107, July 6. T. L. WILLSON and M. M. HAFF. Fertilizer made by mixing phosphate rock with potash and H_3PO_4 and then treating the mixt. with an excess of NH_3 over that required to neutralize the free acid. Cf. C. A. 9, 2282.

U. S., 1,145,370, July 6. L. KERN. Fertilizer is made by mixing raw kieselguhr (containing about 70% SiO_2 , 5% Fe_2O_3 and 4% alkali) with K_2SO_4 , K_2CO_3 or other K

compd., calcining at 100-200° and adding lime and phosphate powder to the calcined mixt. Cf. C. A. 9, 950.

U. S., 1,146,222, July 13. T. L. WILLSON and M. M. HAFF. Dry double superphosphate fertilizer, free from acid, and containing ground phosphate rock combined with pyrophosphoric acid and ammonia. Cf. C. A. 9, 1220.

U. S., 1,146,337, July 13. J. McADAMS. A fertilizer is made by mixing equal amts. of waste molasses and $\text{Ca}(\text{OH})_2$, heating to about 50-5° for 30 min., spreading in a layer and subjecting to a blast of cold, dry air and granulating the product after it has hardened.

Brit., 6,275, Mar. 12, 1914. T. TWYNAM, E. K. SCOTT and F. HOWLES. In mfg. fertilizers, phosphatic basic slags are subjected to the action of the oxides of N and air issuing from a N-fixation furnace, in which the oxides are produced by a high-tension elec. arc, whereby the slag gives rise to a substance containing a sol. phosphate and the nitrates of the bases present in the slag. The temp. of the mass may be controlled to prevent the formation of $\text{Fe}(\text{NO}_3)_3$ by injecting H_2O or steam or a sludge composed of ground slag and H_2O .

Ger., 282,915, Jan. 20, 1914. M. GERLACH. Mfg. fertilizers containing NH_3 and H_3PO_4 by allowing gaseous NH_3 to act on $\text{Ca}_3(\text{PO}_4)_2$ disintegrated by means of H_2SO_4 . Four mols. of NH_3 are used to 1 mol. of the monophosphate of Ca, and by the simultaneous action of the gypsum contained in the superphosphate, $(\text{NH}_4)_2\text{SO}_4$ and $\text{Ca}_3(\text{PO}_4)_2$ are formed. If the disintegrated Ca phosphate is spread out on hurdles, or kept in motion in the chamber by means of stirrers, the process becomes almost quantitative. If small amts. of NH_3 are allowed to react, the conversion is incomplete, and a fertilizer is obtained which is poor in NH_3 . The NH_3 unabsorbed by the superphosphate is recovered by passage through H_2SO_4 and working up to the sulfate. The advantage of the process lies in the fact that NH_3 obtained by the decompn. of CaNCN and nitriles, or by synthesis, can be utilized without the formation of the sulfate.

Ger., 283,133, Jan. 23, 1912. C. PFAUL, NACHFOLGER VON F. BODE. Method of protecting the knives for cutting superphosphate against the attack by the materials under treatment.

Ger., 283,253, Mar. 18, 1913. H. STEIN. Fertilizers are obtained from the slags resulting from the working of Mn, Fe-Mn, and spiegeleisen smelting. The Mn compds. are available in the form of Ca-manganate, or -manganite, or as the double salt, as Ca-Al-manganate-silicate. These salts are insol. in H_2O and therefore retained in the soil. However, by weak acids, e. g., 2% citric acid, the greater part of the Mn is dissolved. H_2O containing CO_2 also has a solvent action when acting for a long period of time, as the Mn-ions go into soln. with the Ca H carbonate. The sepn. of Mn proceeds in proportion to the sepn. of acid from the roots, and is utilized therefore in the nourishment of the plant. To manuf. the fertilizer, Ca compds. are fused together with oxides or salts of Mn at a white heat, a process which is applied on a large scale in the smelting of Mn-ores, Fe-Mn, and spiegeleisen. The slags resulting from this process contain up to 26% Mn, principally in the form of the manganite or manganate of Ca, Mg, and Al. These slags contain also sulfides which are readily converted into H_2SO_4 in the soil and hasten the disintegration of the slags.

Ger., 283,416, July 29, 1914. J. LÜTJENS and W. LUDWIG. Discharging superphosphate from chambers.

Ger., 283,509, Mar. 14, 1913. Addition to 272,915 (C. A. 8, 2669). HOCHOFEN-SCHWEMMSTEIN-SYNDIKAT, G. M. B. H. Disintegrating blast furnace slag of all kinds to form a spongy, porous mass. According to the principal patent, pumice stone, quartz, or like siliceous substances are added to the liquid slag before the latter is poured

into the H_2O . The addition of clay appears to have the same effect, and furthermore increases the strength and firmness of the products made therefrom. So long as the slag is liquid, substances containing SiO_2 and clay are added, and in certain circumstances, readily fusible clay can be employed also. Simple pouring into H_2O , without the simultaneous application of compressed air, is sufficient to cause the slag to become porous.

17. PHARMACEUTICAL CHEMISTRY.

M. I. WILBERT.

Method of preventing the precipitation of tinctures caused by addition of water. ITALO SIMON. Univ. Padua. *Arch. farm. sper.* 19, 439-47(1915).—Tinctures of cinchona, gentian and opium may be dild. with water without formation of a ppt., provided sugar sirup or glycerol is added first. A. W. DOX.

Determination of gum in tragacanth. G. FROMME. *Apoth. Ztg.* 30, 99(1915).—Reply to Otto Frey's criticisms in an article on the same subject (cf. C. A. 9, 2125). W. O. E.

An investigation of the potency of aconite. G. C. ROBINSON. Rockefeller Inst. Hosp. *Arch. Intern. Med.* 15, 645-53(1915).—It was found that large doses (10 cc. 6 times a day) of a tincture of aconite did not produce subjective symptoms and did not slow the heart rate in the tachycardia of exophthalmic goiter. Physostigmine did not augment the effect of the aconite. Although the tincture was not of the chem. standard prescribed by the pharmacopeia, the discrepancy was not sufficient to account for the impotency of the tincture. Physiological assay showed that the activity was less than $1/4$ of that calcd. upon the basis of the chem. assay. The importance of physiological assay is emphasized. I. GREENWALD.

Variations in the toxicity of chloroform for anesthesia. WORTH HALE. *Arch. Intern. Med.* 15, 945-54(1915).—Expts. on mice and brook-trout with 4 different samples of $CHCl_3$ for anesthesia and 1 sample of $CHCl_3$ that had been exposed to light in a colorless bottle for 2 years failed to show any difference in the toxicity. I. G.

Papain: its commercial preparation and digestive properties. D. S. PRATT. *Philippine J. Sci.* 10, 1-33(1915).—A brief review of the properties, uses, native methods of prepn., adulterants, grading, market conditions, etc., of papain is given. *Method of analysis:* Use milk free from butter fat. P. uses a 40% soln. of sweetened condensed skimmed milk. Prepare the enzyme soln. by dissolving 0.75 g. of powdered papain in 150 cc. of H_2O , warming for 30 min. in a thermostat at 40° ; on filtration the active principle is found in the clear filtrate. Well-prepd. gums give a colorless filtrate, which is slightly acid and shows a marked tendency to froth. Measure the milk and H_2O into 150 cc. Erlenmeyer flasks and mix by shaking, add the enzyme soln. from a buret and mix the contents by a few vigorous shakes. Place the flasks at once in the thermostat at 40° ; remove after 30 min. in the same order, add 20 cc. of ice H_2O to each, and place the flasks in melting ice to stop digestion. Wash the contents of each flask successively into a 500 cc. beaker, sufficient H_2O being used to give a final volume of about 75 cc. Ppt. the undigested protein by slowly adding 0.5 cc. of $CuSO_4$ soln. (60 g. per l.), followed by 0.5 cc. of glacial $AcOH$, stirring vigorously. Wash the contents of the beakers into 100 cc. measuring cylinders, let stand a short time to permit the curd to settle, filter on 11 cm. ashless papers previously dried at 100° and weighed. If filtration is slow, do not wait until all the liquid has passed through, but wash the curd back into the cylinders with H_2O warmed to about 60° , disintegrate by means of a rubber-tipped rod and filter, washing 3 more times in this manner, applying gentle suction at the end. Dry to const. wt. at 100° . No correction for the amt. of papain used is necessary,

as it is not pptd. by CuSO_4 and AcOH . The wt. of protein digested by the various amts. of papain may be calcd. from the blank in which no enzyme was used. Detns., except drying, are made in 3-4 hrs.; duplicates agree within about 2%. No anti-septic is necessary with such short periods of incubation. Analyses were carried out as above with commercial samples of papain from various sources. A great divergence in activity was encountered, ranging from gum possessing practically no proteolytic power to highly active material. *Preparation*: Various methods for converting fresh latex into dry papain were investigated, in order to ascertain the extent of deterioration during drying and the possibility of commercially prepg. papain which would exceed the West Indian product in its proteolytic activity. Green fruits were scarified with steel knives in the usual manner, and the juice collected in porcelain evapg. dishes. The entire lot (about 500 g.) was mixed and divided into various portions for study. The fresh latex is considerably more active than dried papain from the Antilles, although both preps. are capable of digesting approx. the same amt. of milk protein with relatively large amts. of enzyme present. The curve for fresh latex shows a rapid increase in digestion with increasing amts. of papain up to about 20 mg. corresponding to 58% digestion of the total protein content, while the West Indian papain gives only 44% digestion at this concn. The fresh latex spread out in porcelain dishes and sun-dried darkened slightly, approximating the West Indian product in color. Analysis gave results approx. the same as fresh latex. It thus appears that sun-dried papain is not necessarily less active than the fresh latex, but, in this case, great care was given the sample to insure rapid drying, exclusion of dust, etc. Small portions of the fresh latex, dried rapidly *in vacuo* over H_2SO_4 , gave a light cream-colored, friable, more porous papain, which showed on analysis little, if any, difference in activity from the original. *Purification*: Mix 20 g. of the fresh latex with 100 cc. of 95% alc., collect the coagulum in a ball, pour off the alc., and replace with 50 cc. of 95% alc.; a fine powder is produced. Filter with suction, wash twice with ether, and dry *in vacuo*, obtaining a perfectly white powder with a faint characteristic odor. (Time from latex to dry papain about 20 min.) This material probably represents the most active papain that could be prepd. commercially, 10 mg. being capable of digesting as much milk protein as 22 mg. of the Philippine sun-dried papain or 40 mg. of the West Indian product. This material is nearly sol. in H_2O , giving an opalescent soln. with small flocks of white insol. matter. The soln. rapidly curdles milk, with the formation of a fine curd that quickly dissolves (use indicated in infant feeding). Expts. with papain from Ceylon on the rate of digestion of milk protein show that digestion proceeded rapidly during the first 10 min. and practically reached its max. within 1 hr. HCl up to 0.06% has only a slight retarding action on the digestion of milk protein; increasing amts., from 0.06 to 0.13%, acid, very greatly reduce the activity of the enzyme, although any further increase up to 0.2% causes practically no change. A sharply defined range of acidity thus reduces the digestion to 0.5, its former value. NaHCO_3 in amts. ranging from 0.0 to 0.2% had no effect on the digestion of milk protein; similar negative results were obtained with concns. of NaCl varying from 0.10 to 1.0%. Expts. with HCN to det. its effect on the digestion of milk protein by pure papain gave results in accord with the data given by Mendel and Blood (cf. *C. A.* 5, 95). Expts. with papain prepd. by the alc. pptn. method were carried out at temps. ranging from 0° to 70° ; all digestions were for 30 min. periods. Papain shows a remarkable activity at low temps.; the results are plotted. There appears to be very little difference in the rate of digestion in the neighborhood of 40 to 50° . The digestions at 70° show that the activity in the presence of large amts. of enzyme is not greatly weakened, but with decreasing percentages of gum the loss becomes more marked. A papain soln. rapidly heated to 100° , let boil 5 secs., and immediately cooled with ice no longer shows any proteolytic activity. *Evaluation of papain*: It is suggested that the average of 6 detns. made as under "method of anal-

ysis," using 25 cc. of milk, 23 cc. of H_2O , and 2 cc. of a filtered soln., representing 10 mg. of papain, digested for 30 mins. at 40° , be accepted as the standard and that the proteolytic activity of the gum be designated by the ratio so obtained of 1 part of papain to the digested protein. This is called the "activity no." of the sample. Investigations with the fresh papaya latex showed absence of invertase and diastase. It is probable that the reported presence of the latter in com. papain is to be attributed to the adulterants used in its prepn. A considerable amt. of a peroxidase is present in the fresh latex and causes the darkening of color on drying. The presence of lipase could not be definitely established, though the possibility of traces was indicated. Cf. C. A. 8, 968; MacMillan, C. A. 9, 1529. F. W. SMITHER.

Further steps toward uniformity in the official preparations of digitalis. FOCKE. *Z. exp. Path. Ther.* 16, 443-66(1914).—A review of recent publications on the biological testing of prepn. of digitalis with a report of expts. on the testing of digitalis and of strophanthus. Focke concludes in part that in Germany the several *Temporaria* are well suited for the testing of digitalis, either on the isolated heart or the intact animal. The values found for the *Temporaria* are applicable to man. The isolated frog heart method, despite recent improvements in the technic, is still too difficult for general use. For use with the intact animal the method of detg. the av. dose is most satisfactory. For ordinary purposes it is not necessary or even desirable to extract digitalis leaves completely. M. I. W.

Digitalis dosage (EGGLESTON) 11H.

U. S., 1,145,487, July 6. A. KAUFMANN. 6-Methylhydroxyquinolyl methyl ketone is made by reacting on 6-methylhydroxy-4-cyanoquinoline with Mg methyl iodide and decomp. the addition product thus formed by treatment with H_2O . It forms yellow needles, when crystd. from ligroin, m. 92° . 4-Cyanoquinoline with Mg phenyl bromide yields quinolyl 4-phenyl ketone distg. at 145° under a pressure of 0.12 mm., sol. in alc., ether and C_6H_6 , and forming a brownish yellow picrate, m. 214° , and a yellow phenylhydrazone, m. $239-40^\circ$. 4-Cyanoquinoline with Mg methyl iodide yields quinolyl 4-methyl ketone, an oil boiling at about 106° under 0.2 mm. pressure, forming a picrate, decomp. $165-70^\circ$, and a dark red cryst. iodomethylate, m. at 172° .

U. S., 1,145,634, July 6. R. UHL. Copper compounds of thio-protein substances are made by dissolving a protein substance, *e. g.*, peptone, casein or serum albumin, in NaOH soln., filtering, adding CS_2 to the filtrate and then adding an ammoniacal soln. of $CuSO_4$, pptg. with acetone, redissolving the ppt. with KOH and repptg. with alc.-ether. The product is dark brown, sol. in H_2O and alkalis and is not pptd. by NaCl or blood serum. It is adapted for use as an antiseptic and therapeutic against *Staphylococcus aureus*, etc.

U. S., 1,146,014, July 13. R. G. MEWBORNE. Concentrating solutions or extracts containing free nicotine by distg. off H_2O in a high vacuum and passing the vapors through a rectifying column from which any nicotine vapor which is produced is returned to the still after condensation.

U. S., 1,146,142, July 13. C. ELLIS. Benzyl chloride is made by vaporizing toluene and PCl_5 , adding Cl sufficient to combine with only part of the toluene and heating the mixt. to about 200° while subjected to the action of ultraviolet light. The $BzCl$ formed is condensed from the HCl and other residual constituents of the mixt., and the latter with the PCl_5 are returned for further treatment, the HCl formed being sep'd. and fresh toluene added as required.

Brit., 7,418, Mar. 24, 1914. CONSORTIUM FÜR ELEKTROCHEM-IND. GES. Acetic acid is manufd. by oxidation of aldehyde by means of air or O in the presence of a catalyst consisting of Mn formate, acetate, butyrate, benzoate, or lactate, or the Mn salts of similar organic acids. Cf. C. A. 9, 355.

Dan., 18,904, May 16, 1912. AKTIEBOLAGET "ASTRA." Mfg. carbohydrate-phosphoric acid alkyl esters and their salts. Most of the *Saccharomyces* varieties and the fermentable sugars can be employed for the manuf. of the alkyl esters, if to the living yeast such compds. are added as can retard the fermentation. The prepn. of the Ca salt is as follows: 100 g. crude sugar, dissolved in 250 cc. H₂O, are mixed with 150 g. compressed-yeast (*i. e.*, yeast containing 30% dry matter), and 10 cc. toluene. After 10 min. a soln. of 75 g. Na₂HPO₄, dissolved in 300 g. H₂O, is added. After 4 hrs. all free phosphate has disappeared. The yeast is then filtered off, and the soln. is freed from the albuminous substances formed by the yeast by heating the liquid to 60°. Then to the filtrate is added so much of a satd. soln. of a Ca salt that for every mol. H₃PO₄, 1 atom Ca is present. Finally, a corresponding amt. of 90% alc. is added, and the liquid is allowed to stand for several hrs. The Ca salt and the carbohydrate-phosphoric acid ester are filtered off and washed with dil. alc. The phosphate is converted in this manner quantitatively into carbohydrate-phosphoric acid alkyl esters. The theory is 44 g. alkyl ester and 75 g. Na monophosphate. Practically 38 g. and 75 g. are obtained.

Ger., 279,313, Jan. 3, 1912. E. SACK. Mfg. a ketone from civet with a musk odor, by preheating the civet with alkali, and then distg. with steam. The residue is extd. with ether or an equiv. solvent, the ext., after evapn of the solvent, is treated with a little alc., filtered from the undissolved portion, and the ketone is sepd. from the soln. by means of semicarbazide or by other known methods. The product has the compn. C₁₇H₃₀O, freezes at 32.5°, b₁₇ 204–205°, and forms a semicarbazone, m. 187°. According to claim 2 the civet is distd. with concd. KOH or NaOH, while maintaining the concn. of the reaction mixt., and then the oil distillate treated with semicarbazide as specified.

Ger., 281,098, Oct. 9, 1913; Brit., 23,945, Oct. 22, 1913. CASSELLA & Co. Mfg. diazo salts in solid form by diazotizing the aromatic amines in concd. H₂SO₄, partly neutralizing the soln. with MgO or MgCO₃, and then adding an alkali sulfate.

Ger., 281,551, July 15, 1911. F. HOFFMANN-LA ROCHE & Co. Mfg. products rich in iron from higher unsatd. halogen fatty acids by melting the latter (diiodotarinic acid, dibromostearic acid) with more freshly pptd. Fe₂(OH)₃ than is necessary for the formation of the normal salts of these acids. In this manner are obtained therapeutically active products containing 25% and more of Fe. These Fe-rich products, as well as those of a lower Fe content, are to be regarded as solns. of Fe₂(OH)₃ in the normal Fe salt (Fe(C₁₈H₃₁O₂I₂)₂).

Ger., 282,002, Jan. 30, 1913. F. HOFFMANN-LA ROCHE & Co. Sepg. the pharmacologically active constituents of the pituitary body by grinding up the glands, as such, or the exts. obtained therefrom, with Na₂CO₃, extg. the resulting powder, first with CHCl₃, then with alc., and evapg. the acidified ext. to dryness. In this manner 2 pharmacologically different constituents of the pituitary gland can be sepd. and converted into dry products, free from inactive constituents.

Ger., 282,097, May 18, 1913. BAYER & Co. Mfg. bromodiethylacetylcarbamide by acting on diethylacetyl isocyanate with Br and treating the resulting product with saponifying agents, such as H₂O, aq. NH₃, and the like.

Ger., 282,108, May 17, 1914. I. BUGARSZKY and L. TÖRÖK, and KERESZTY and WOLF. Separating the constituents of oleum cadinum, especially that portion b₂₀ 220–300° known as cadogel and applied in the treatment of skin diseases. When the oil, or

cadogel, is subjected to fractional soln. or washing with MeOH, it is sepd. into 2 distinctly different constituents; the portion readily sol. in MeOH consists of 1 or more compds. contg. O, while the portion difficultly sol. in MeOH consists of 1 or more hydrocarbons. By repeated fractional soln., with interposed fractional vacuum distn., these 2 products can be sepd. more completely from each other. The portion scarcely sol. in MeOH, after distn. over Na metal, consists of a clear, colorless liquid with strong reducing properties, the compn. of which corresponds to the formula $C_{20}H_{10}$. This product, as well as the portion contg. O, serves as initial material in the manuf. of pharmaceutical preps. Acetone (92%) or EtOH (93%) can be used as solvents instead of MeOH. Cf. C. A. 9, 955.

Ger., 282,133, July 10, 1913. FARBW. v. M. L. & B. Mfg. nucleus-chlorinated aromatic carboxylic acids by heating sulfonic acids of the aromatic series, or their salts, which contain the Me group in the nucleus, with thionyl chloride, with or without the addition of indifferent solvents, to temps. above 200° , and treating the resulting reaction products in the heat with H_2O , alkalis, or dil. acids. E. g., *o*-toluenesulfonic acid may be converted readily by this means into the *o*-chlorobenzoic acid, and the *p*-chlorobenzoic acid may be obtained from *p*-toluic acid.

Ger., 282,134, June 21, 1913. A. HOCHSTETTER. Mfg. chloroformic acid esters, according to the process of Barral and Morel. Phenol is dissolved in H_2O with alkali, and a soln. of $COCl_2$ in a solvent not miscible with H_2O is added—operating in a two-phase reaction mixt. which consists of H_2O and a solvent not miscible therewith. The hydroxy compd. used (alc., phenol) is dispersed between the layers of the two-phase mixt. in such manner that it is contained almost entirely in the non-aq. layer containing the $COCl_2$, or at least shows a marked concn. there. With an alc. readily sol. in H_2O is chosen a solvent, not miscible with H_2O , into which the alc. in question passes from the H_2O to a large extent. The entire amt. of $COCl_2$ to be used is added to the reaction mixt., and then the alc. is introduced gradually, or the $COCl_2$ is added a little at a time. The non-aq. phase of the reaction mixt. can be formed of the chloroformic acid ester which is to be produced, or of $COCl_2$ itself if operating under pressures and temps. at which $COCl_2$ is liquid. In cases in which the dispersion coeff. between the two layers of the alc. to be esterified is not very favorable, the addition of NaCl, $CaCl_2$, or the like, to the aq. layer is necessary. In case the liberated HCl can influence the yield, alkalis or $Ca(OH)_2$ or $CaCO_3$ may be dissolved or suspended in the aq. layer.

Ger., 282,263, Jan. 25, 1914. AKT.-GES. FÜR ANILIN-FABRIKATION. In the concentration of dilute acetic acid, 100 g. 70% HOAc are mixed with 500 g. metaphosphoric acid, the mixt. is heated on the steam bath for 30 min., distd., then fractionated. A 99% HOAc is obtained. The residue is reconverted into metaphosphoric acid by heating.

Ger., 282,264, May 18, 1913. I. ABELIN, E. BÜRG and M. PERELSTEIN. 4-Dimethylamino-1-phenyl-2,3-dimethyl-5-pyrazolone compound of *p*-aminophenyl ω -dimethylaminosalicylate, an antipyretic narcotic compd. of the formula $C_{27}H_{30}O_7N_4S$, decomg. at $141-142^{\circ}$, is prepared by the action of 4-dimethylamino-1-phenyl-2,3-dimethyl-5-pyrazolone on ω -methylsulfonic acid of *p*-aminophenyl salicylate.

Ger., 282,265, Dec. 7, 1913. BAYER & Co. Unsaturated acids of the anthraquinone series are obtained by condensation of anthraquinone-2-aldehyde or ω -dihalogen-2-methylantraquinone or their derivs. with acetates. These products serve for the production of dyes and medicinal preps., as e. g., the heretofore unknown *anthraquinonyl-2-acrylic acid*.

Ger., 282,266, Dec. 25, 1913. FARBW. v. M. L. & B. The manuf. of amyl acetate. By the action of Al amylate on acetaldehyde in amyl alc. soln., instead of the expected

EtOAc, amyl acetate and EtOH are obtained, *i. e.*, the lower homologous alc. is expelled by the higher homolog, contrary to the assumption of Kremann. *E. g.*, in 100 parts of isoamyl alc., 10 parts of Al isoamylate are dissolved, or, with the aid of a little Hg, 1 part of Al is dissolved, and into the cooled soln. (temp. below 18°), 100 parts of acetaldehyde are allowed to flow, with stirring. After standing for 12 hrs., the mass is fractionated, whereby from the high-boiling fraction 110–120 parts of amyl acetate are obtained.

Ger., 282,296, Sept. 19, 1913. FRAU MATHILDE GROLL. Manuf. of permanent fermentation preparations, especially of lactic acid bacteria, in convenient culture form for transportation. The moist mass is made, not from ordinary sugar, but from sugar, the crystallizing power of which has to be minimized or destroyed, *i. e.*, from so-called fondant-sugar which is made by boiling down ordinary sugar to 40–45° of the sugar scale, washing repeatedly to prevent crystn., adding some potato or grape sugar, pouring on to a marble plate, spraying with H₂O, cooling well, and finally making it into tablets. By this treatment the sugar becomes completely sterile, loses its crystg. property, becomes doughy and does not dry out, retaining 22–24% moisture for a very long time. The product dissolves readily in a great number of liquids and may be combined intimately with bacteria cultures and their culture media, as well as with dyes, ethers, etc. These mixts., after incorporation of the bacterial culture, constitute a sterile mass completely free from foreign organisms and, by virtue of their retained moisture, impart permanency to the life and germinating power of the ferments.

Ger., 282,313, Nov. 19, 1913. BAYER & Co. Water-soluble condensation products, used in the manuf. of therapeutic preps. and as tanning agents, are obtained by dissolving di- or trihydroxybenzenes, etc., wherein at least 1 *p*-position, with respect to the OH group, is not substituted, in an indifferent solvent (H₂O or alc.) at a low temp., mixing this soln. with acetaldehyde and its derivs., and allowing the mass to react, with the addition of acid or basic condensing agents, and with gentle warming.

Ger., 282,320, July 31, 1912. W. WIECHOWSKI and O. ADLER. Mfg. a permanently stable laxative, locally active in the intestines, by pptg. with aq. solns. of colloidal Fe₃(OH)₃, at a high temp., vegetable laxative infusions prepared in the usual manner, adding animal black to the filtrate, sepg. the animal black, which contains the active substance, from the supernatant liquid, washing with H₂O, and drying at the ordinary temp. *E. g.*, 50 g. powdered rhubarb is made up into a hot effusion which is strained and mixed with 100 cc. of a soln. of colloidal Fe₃(OH)₃ and brought to a boil. After sepg. the solids, 50 g. pure animal black is stirred in, and the liquid above the rapidly settling animal black is drawn off. The black is then washed thoroughly with H₂O and dried at a moderate temp. There is obtained a black, odorless and tasteless powder possessing uniformly permanent properties.

Ger., 282,376–7, Dec. 31, 1913. L. ROSENTHALER and A. ABELMANN. Mfg. mercurous compounds of basic purine derivatives by allowing mercurous salts, as HgNO₂, in aq. soln., to act upon acid solns. of basic purines, as caffeine, theobromine or theophylline in HNO₃. In this manner are obtained the heretofore unknown mercurous derivs. of basic purine derivs., which are but slightly poisonous, and therefore applicable in the eradication of diseases due to spirochaetes and spirilla. If theobromine or theophylline, in acid soln., be treated with Hg acetate, or if the aq. suspension of theobromine or theophylline be heated in the presence or absence of alkali lyes, with HgO, mercurized compds. of basic purine derivs., *e. g.*, (C₇H₇O₂N₄)₂Hg, are obtained. These also are but slightly poisonous, and are applicable therapeutically.

Ger., 282,455, Sept. 16, 1913. BAYER & Co. Mfg. hydroxyquinoline compounds containing iodine and bismuth, their nucleus and substitution products, by boiling

these compds., *e. g.*, 8-hydroxyquinoline, 5-bromo-, 5-methyl-8-hydroxyquinoline, with the calcd. amt. of BiOI in aq. suspension, for several hrs., and extg. the ppt. with alc. and ether. The product is strongly antiseptic.

Ger., 282,456, Oct. 21, 1913. BAYER & Co. Mfg. alcohols of the pyrrolidine series. Acidylized pyrroles of Formula I, in which R = alkyl, may be reduced as readily in the nucleus as in the side chain. 2-Acetylpyrrole, dissolved in 10 parts alc., is reduced in the usual manner with Na in boiling soln., and goes over into the pyrrolidine alc. of Formula II. These amino alcs. are applied as initial material in the manuf. of pharmaceutical products.

Ger., 282,457, June 20, 1913. Addition to 276,636 (C. A. 9, 356). A. KAUFMANN. In mfg. ketones of the quinoline or isoquinoline series, the principal process, as applied to 4-cyanoquinoline, may be applied generally with the cyano derivs. of the quinoline and isoquinoline series which contain the CN group attached to the pyridine ring in the *o*-position to the N. *E. g.*, Mg alkyl halides are allowed to act on quinoline-2-carboxylic acid nitrile or isoquinoline-1-carboxylic acid nitrile, and the resulting addition products are broken down in the usual manner. The heretofore unknown quinolyl-2- and isoquinolyl-1-alkyl ketones of the following constitution serve for manuf. of medicinal preps. and are themselves applicable in perfumery.

Ger., 282,492, Oct. 2, 1913. FARBW. v. M. L. & B. In mfg. aromatic amines, aromatic nitro compds., which are volatile with steam, permit of ready reduction in the presence of H by distn. in a current of steam over suitable catalyzer for carrying the H (Ni, Pd, Pt). The reaction is effected under the b. p. of the nitro compd. *E. g.*, for the manuf. of aniline, a current of steam and H is led through the nitrobenzene heated to about 120°. A long, horizontal tube, half filled with finely divided Ni and heated to about 120°, is used as the reducing app.

Ger., 282,494, Dec. 23, 1913. F. ULLMANN. 4-Chloro-1-hydroxyanthraquinone and its derivs. are obtained by chlorination of 1-hydroxyanthraquinone or its derivs. with SO₂Cl₂ in the presence or absence of catalyzers such as I, with the aid of heat. By the further action of SO₂Cl₂, with the addition of catalyzers, polychloro derivs. are obtained.

Ger., 282,790, Nov. 22, 1913. C. BÜCKEL. Mfg. salves, lubricants, and the like, by mixing acidylarylsulfonimides or their alkali salts, alone or in the presence of soap, with hydrocarbons, oils, fats, or fatty substances. The property of the acidylarylsulfonimides of forming salts with alkalis is of great significance in connection with emulsions for spraying wool for later dyeing of the textiles in the piece, because the emulsifying agent can be washed out, thereby preventing an uneven taking of the dye, clouding, subsequent odor on storing, and the like. Furthermore, by the addition of acidylarylsulfonimides the fats, oils, and fatty substances acquire an increased m. p., which is of value when these mixts. are to be employed as lubricants. *E. g.*, a vaseline (5 kg.) of a m. p. of 35°, does not m. below 75° when 1 kg. palmityl-*p*-toluenesulfon-

imide is added. Olive oil, 10 kg., after the addition of 1 kg. stearyl-*p*-toluenesulfonimide, forms with 3 kg. H₂O a permanent white salve. If 6 kg. NH₄ compd. of palmityl-*p*-toluenesulfonimide and 12 kg. of a 60% soap are boiled up with 200 liters H₂O, 30 kg. CCl₄ added with stirring, and the whole dild. to 1000 liters, a permanent emulsion is obtained. A yellowish white emulsion is obtained by mixing 45 kg. of cod liver oil with 5 kg. NH₄ compd. of palmityl-*p*-toluenesulfonimide, and then stirring up with 50 liters H₂O.

Ger., 282,791, Dec. 13, 1913. Addition to 282,790 (*supra*). C. BÜCKEL. Salves, lubricants, and the like, prepd. by means of alkali salts as specified in the principal patent, can also be obtained by means of the alk.-earth and heavy metal salts of acidyl-arylsulfonimides. *E. g.*, Na compd. of palmityl-*p*-toluenesulfonimide yields white salts with CaCl₂, AgNO₃, and HgCl₂, a light greenish salt with CuSO₄, and a bright yellow salt with Fe₂Cl₆. These salts impart to oils, fats, and fatty substances, the property of yielding permanent emulsions with H₂O. *E. g.*, 9 parts olive oil, after the addition of 1 part Ca salt of palmityl-*p*-toluenesulfonimide, forms with 3 parts H₂O a stable yellowish white salve.

Ger., 282,792, May 5, 1914. J. SCHRIDIG. Mfg. a sterile court-plaster from animal skin, such as the cheap intestinal membranes, by washing and scraping off the fat, treating with powdered burned pyrolusite, rubbing off with powdered pumice, and finally cleaning with a disinfectant, preferably sublimate soln., whereupon the dried skin is coated with gum arabic soln., or the like. The outer skin of the ox rump is especially suitable. Pyrolusite not only absorbs the fat remaining on the skin, but also dries the skin when finely ground pumice is rubbed on.

Ger., 282,819, Nov. 21, 1913. CHEM. FABRIK H. WERTZ. Mfg. salts of boroformic acid by allowing H₃BO₃ and HCOOH, in the free state or in the form of their alkali salts, to react in the presence of alkalies or alkali carbonates. Na boroformate, m. 110–111°, is obtained, *e. g.*, from a soln. of 431 g. crystd. soda and 575 g. borax in 1250 cc. warm H₂O, by introducing, slowly, 347 g. of 80% HCOOH, or by crystg. an aq. soln. of 409.7 g. NaOCO.H and 373.4 g. H₃BO₃, or finally by crystg. 744.0 g. H₃BO₃ and 1716.0 g. soda in H₂O, after the addition of 552.0 g. HCOOH. These alkali salts of boroformic acid (the K salt can be obtained in an analogous manner) have therapeutic application.

Ger., 282,986, Feb. 28, 1913. Addition to 278,868 (C. A. 9, 1096). HENKEL & CRE. Zinc perborate can be obtained by a method analogous to that specified in the principal patent for the manuf. of Mg perborate. *E. g.*, 1 mol. ZnSO₄·7H₂O is intimately mixed with 2 mols. NaBO₃·4H₂O and the mixt. is fused on the water bath at about 70° and kept at this temp. for a long time with stirring. The mass solidifies rather rapidly after cooling, has a uniform granular appearance and may be pulverized easily after thorough drying. The product is a perfectly white amorphous powder of homogeneous compn. The yield of active O is almost quant., and the stability is very satisfactory. The Zn perborate, in consequence of its high O content, in combination with the action of the Zn-boric acid compd., is applied pharmaceutically.

Ger., 283,649, Mar. 8, 1914. CHEM. FABRIK HELFENBERG A.-G. v. E. DIETERICH. A permanently dry calcium chloride preparation is made with the aid of Chinese gelatin agar-agar. The soln., emulsion, fine powder or crushed mass of CaCl₂ is taken up by means of fine cut or coarse agar-agar, adding the CaCl₂ a little at a time. *E. g.*, 500 g. agar-agar cuttings can be worked up with 2000 g. H₂O in which 100–500 g. crystd. CaCl₂ have been dissolved according to the strength of CaCl₂ desired. In the animal body the CaCl₂ is taken from the prepn. and metabolized, while the agar-agar passes off unchanged.

Ger., 283,728, Dec. 3, 1911. R. VON WALTHER. Mfg. powders and salves with increased covering power. Cf. Fr., 451,446 (C. A. 7, 3532).

The Italian chemical industry and the war. ANON. *Chem. Ztg.* 39, 489-91 (1915). J. H. MOORE.

The Austro-Hungarian chemical industry and the war. ED. DONATH AND G. ULRICH. Brunn. *Chem. Ztg.* 39, 505-7, 526-8 (1915). J. H. MOORE.

The fixation of atmospheric nitrogen on a commercial scale. H. C. PRINSEN-GEERLIGS. *Louisiana Planter* 54, 347-8 (1915).—P.-G. reviews various known methods for the fixation of N and refers to the work of the German Fermentation Industry Inst. in connection with the conversion of the N of NH_3 unto albuminoids. Under suitable conditions, yeast is rapidly grown in a soln. of sugar, $(\text{NH}_4)_2\text{SO}_4$, and some nourishing salts by forcing a current of air through the liquid. A considerable amt. of organic matter is formed and when dried contains about 40% albumin and is equal in wt. to the sugar used. When mixed with molasses, a complete cattle food is produced.

A. GROSS.

Deacon process. B. NEUMANN. *Z. angew. Chem.* 28, I, 233-6 (1915).—Results are given of investigations of the effect of catalytic agents on the equil. $4\text{HCl} + \text{O}_2 \rightleftharpoons 2\text{H}_2\text{O} + \text{Cl}_2$, made with a view to increasing the yield of Cl_2 . It was found that the double salts of CuCl_2 and KCl or NaCl gave better results than the CuCl_2 alone. Theoretically the process must be carried out at as low a temp. as possible, which, however, would result in reaction velocities too slow for practical use. The greatest degree of decompn. takes place when the entering mixt. of air and HCl contains a low % of HCl , but then the Cl conc. in the final mixt. is low for practice. When CuCl_2 is used as the catalyst the most efficient temp. is 430° , for the double salts about 40° higher; the latter do not volatilize as readily. The degree of decompn. is increased by the use of O_2 instead of air, but the increased yield does not warrant the higher cost of the O_2 . The double salt copper chloride-sodium chloride begins to volatilize at about 550° in a quiet atm. and at approx. 510° in a current of gas, while CuCl_2 begins to volatilize between 430 and 460° . The reaction velocity at 470° is so great that with mixts, rich in HCl the state of equil. is reached in a short time, when the double salt is used as the catalyst.

H. R. GUNDLACH.

Ammonia-soda: Striebeck system. K. W. JURISCH. *Chem. Ind.* 38, 9-22, 61-71 (1915); cf. *C. A.* 1, 228, 473-4; 4, 3123; 5, 2308.—Developed by Striebeck in the period 1879-1885 this unpatented process was kept secret till his death in 1900. The output of factories at Nürnberg, Inowrazlaw and Stassfurt exceeds that of all others operating according to systems other than the Solvay system. A detailed description with plan is given of one unit for the production of 30,000 kg. per day. Two active and one reserve CaO kilns, each burning 27,000 to 30,000 kg. per day, are required. These kilns have an oval or round cross-section, about 3 m. in external diam. at widest part, about 10 m. high and are so supported on 4 cast Fe columns that the lower discharge end is 80 cm. above ground level, its opening being closed by a "plug" of burnt CaO . The burning is effected exclusively with coke mixed with the CaO . Around the head of the CaO kiln is a circular canal 1 m. high and 30 cm. wide in which the gas collects and some dust settles. The gas is drawn through a vent in upper part of the canal through a cast Fe pipe 40 cm. in diam. into a dust trap and then into a scrubber. Each CaO kiln has its own scrubber which rests upon a base 50 cm. high and is 8.5 m. high with a diam. of 1.5 m. The gas enters below a perforated false bottom about 75 cm. above the true bottom. The gas main provided with large side openings is extended into the scrubber which is packed with coke, broken tile or similar material above the false bottom and constantly washed by a descending stream of H_2O distributed

by means of specially constructed floating rubber balls. The outflow is so regulated that a definite height of H_2O is maintained below the grid. The scrubber cools the gas and removes dust, SO_2 and tarry matter, etc. The gas is drawn from the upper space of the scrubber through a cast Fe pipe 25 cm. diam. into a separator or second scrubber without filling 3.6 m. high and 1.5 m. diam. to remove entrained water, $NaCl$, $CaCl_2$, $MgCl_2$, which form crusts with lubricating oil of the compressor. The gas enters below through a sieve about 45 cm. above the true bottom. The gas passes through a 225 mm. diam. cast Fe pipe to the 3 compressors, 2 of which are always in use. Each machine sucks under a negative pressure of 7 to 8 cm. of Hg about 24 cu. m. of gas per min. calcd. to atm. pressure. The gas is compressed to about 1.6 atm., cooling with a spray of H_2O . The compressed gas passes through a 200-mm. diam. cast Fe pipe into a H_2O separator 1.2 m. in diam. and 1.5 m. long with arched end plates, then into an air-chamber about 2.4 m. high and 1.2 m. diam. in which a further sepn. of H_2O occurs. From here the gas passes direct to the pear-shaped Fe or steel carbonators, 6 for one unit, 6.2 m. high and 5 m. in diam., supported by 6 cast Fe columns, apex resting on a base on ground. The walls are 10 mm. thick in lower part, 9 in. upper. A novel feature is a distributing system with 6 radial slotted arms. The slots soon become clogged, so to prevent stoppage of gas flow by the deposited $NaHCO_3$, these 6 distributing arms are Ω -shaped and so kept open below. The overflow pipe is horizontal, 150 mm. in diam. and serves both to remove bicarbonate slime, and charge the app. with fresh ammoniacal brine; the excess of free NH_3 readily dissolves any obstructing lumps of $NaHCO_3$. The 6 carbonators are divided into 2 groups of 3; each group receives a stream of CO_2 from the blowing engines; the gas then passes through a scrubber to be freed from entrained NH_3 . After a carbonator is emptied, it is recharged with 40 cu. m. of fresh ammoniacal brine and connected at the end of the series of 3. One carbonator is emptied and recharged every 8 hrs. since 40 cu. m. of the brine requires 24 hrs. for satn. with CO_2 , producing 5,000 kg. of soda. The temp. at the end of carbonation is $20-28^\circ$. The carbonators are not lined as a protective layer of $NaHCO_3$ forms on the inner walls. The exit gases, the gas from the vac. filters and the waste gases from the absorption vessel in the distn. are washed in a scrubber with brine, passing finally through H_2SO_4 to remove last of the NH_3 . To effect rapid and complete emptying of the carbonators the bicarbonate slime is forced into a closed, steel, stirring chamber of 5 m. diam. and 2.5 m. height, capacity 49 cu. m., having a stirrer of 2 to 3 h. p. The exit pipe for the slime is near the bottom of the stirrer and is 100 mm. in diam.; the slime flows by gravity onto 10 of the battery of 20 vac. filters, 1.6 m. sq. base and 1.35 m. high; the filtering layer is about 70 cm. from the bottom. While filling with bicarbonate slime the filters are covered and sealed by a H_2O layer; filling, filtration and washing are done without using suction. Each filter has a 500 l. elevated water tank for washing; 2 or 3 washings with cold H_2O ($1\frac{1}{2}$ vol. of H_2O to 1 of slime) suffice. The filters in series of 2 or 3 are sucked dry with a vacuum of not less than 25 cm. Hg. Each 40 cm. thick, filter cake yields in 6 hrs. about 1,024 cu. m. of bicarbonate. Gases from each filter are sent with the exit carbonator gas to the scrubber. The filtrate and washings are collected in an Fe holder; the bicarbonate settling out is removed from time to time and treated as the other bicarbonate. Calcination is done by Thelen pans of 5 parts, each 1.6 m. long, closed in order to recover CO_2 and NH_3 , provided with stirrers. Yield 6,000 kg. Na_2CO_3 per 24 hrs. from the moist $NaHCO_3$ from the vacuum filters; 6,500 kg. soda from centrifuged $NaHCO_3$. The gases are conducted through a horizontal cooled pipe to remove dust with the condensed H_2O . The gases from 3 pans then pass into cooling "boats," then mix with the ammoniacal waste gases from the clarification vessels for ammoniacal brine and finally pass into the absorption vessel of the distn. app. at a pressure of 0.7 atm. To produce a denser Na_2CO_3 (d. about 1.4), the product is calcined in an ordinary furnace till partially fused

and the mass powdered. The *mother liquor* and *washings* are pumped up into metal holders 14 m. above the brine supply, holding 5 to 10 cu. m. and operated in pairs. A pipe passes from these vessels to the upper part of a ten-compartment preheating column and is also connected with the mother liquor pump. The column is heated by the steam from the main column and the hot NH_3 vapors from the mixing vessels. The soln. free of volatile NH_4 compds. now flows into the mixing or decomposing vessel, where it is mixed with milk of lime. A thin milk of $12\text{--}13^\circ \text{Bé.}$ is prepd. in slaking vessels; the steam is piped off for use in the distn. The milk is passed through a settling box to remove coarse material and then into a stirrer, then into 2 vertical cylinders with conical bases where heavier matter settles and is drawn off at bottom. It then flows into thickeners whence thickened Ca(OH)_2 is drawn off just above the bottom and discharged into the cast iron decomposing vessel of the Honigmann type. The narrow, rectangular, main column, 11.55 m. high, contains 36 compartments so arranged that on the narrow sides, stages 25 cm. apart are present, while on the long sides landings are 50 cm. apart. Steam from the blowing engines under a pressure of 1.1–1.2 atm. passes into the main column at top, flows out and mixes with vapor from the mixing vessels, passes through the preheating column into the cooling "boats," and the NH_3 is conducted to the brine vessel. *Raw materials:* NaCl averages about 96.5–97.5% NaCl; limestone in Stassfurt 90% CaCO_3 ; Striebeck claimed 95–98% $\text{CaCO}_3 + \text{MgCO}_3$. NH_3 in the form of $(\text{NH}_4)_2\text{SO}_4$ made from gas liquor. The av. of the gas from the CaO kilns was 26% by vol. of CO_2 . Exit gas from carbonators averaged 13% by vol. of CO_2 . Gas from the calcination was 50–60% by vol. CO_2 —Striebeck obtained as high as 80–90% at Inowrazlaw. About 75% of the CO_2 is absorbed in the receivers. End gases contained about 10–12% by vol. of CO_2 and about 0.005 kg. of NH_3 per cu. m. About 2.9 kg. of H_2SO_4 of 66°Bé. are used for recovery of NH_3 in the final absorber per 100 kg. of Na_2CO_3 . Ammoniacal brine in the absorption vessel contains only 260–270 g. NaCl per l. and is considerably undersatd. with but 63–68 g. NH_3 per l.

F. W. SMITHER.

Manufacture of nitrite of soda. J. TURNER. *J. Soc. Chem. Ind.* 34, 585–6 (1915).—The method based on the reduction at 420° of NaNO_3 by means of Pb is first described. By careful regulation of the process 90% of the theoretical yield of NaNO_2 may be obtained. The Paul process described in detail, based on the cautious reduction of NaNO_3 by NaOH and S, is not so cheap as the Pb process, on account of the difficulty in sepg. the Na_2SO_4 from the NaNO_2 , and the max. yield is only 80% of theory.

Valuable potassium compounds in Catalonia (Spain). C. B. HURST. *Commerce Reports* 1915, Supplement 15c, 10–12.—In view of the discontinuance of potash exports from Germany, the extensive potash deposits near Barcelona have been investigated. These are briefly described.

E. J. C.

Vapor-compression refrigeration. J. H. GRINDLEY. *Engineering* 100, 22–4 47–8 (1915).—A short account of vapor-compression refrigeration is presented in Part I and some variations of the manner in which present-day vapor-compression machines effect their object are discussed, using for this purpose the entropy-enthalpy diagram. It is concluded that the mechanical complication involved in carrying out some of the cycles, which theory suggests give increased performances, may not warrant their practical application but undoubtedly some of them would be possible and practicable, especially when dealing with high-temp. condensing H_2O , and when cooling has to be carried out at temps. above the critical point. In Part II graphs for showing the properties of CO_2 and NH_3 are given and explained. There are found three curves, one or more of which may be straight, on which to place scales of the 3 variables p , v , and T , and these 3 curves are so placed in relation to each other that the scaled values of any

3 points, one on each curve, which are collinear, give simultaneous values of p , v , and T , which satisfy the desired equation. Cf. *C. A.* 7, 1083; Goodenough and Mosher *C. A.* 7, 3202. F. W. SMITHER.

Air-lift pumping. P. H. BERGGREEN. *Sibley J. Engineering* 1915, May; *Met. Chem. Eng.* 13, 507(1915).—A résumé of this subject. E. J. C.

Brit., 6,274, Mar. 12, 1914. H. POLLARD. Ammonia is obtained in the anhydrous liquid form, without employing a mechanical compressor, by first absorbing the gas by means of a dry salt, which produce a liquid combination, and then expelling the NH_3 by heat under sufficient pressure to effect its liquefaction.

Brit., 6,288, Mar. 12, 1914. F. RASCHIG. A packing for absorption or reaction towers consists of small cylinders irregularly arranged, as by dropping or pouring them into the tower.

Brit., 6,354, Mar. 12, 1914. SOC. ANON. DES COMBUSTIBLES INDUSTRIELS. Carbon is obtained from liquid hydrocarbons, such as coal tars, tar oils, petroleum tars or oils, by first removing any suspended mineral matter and then subjecting the hydrocarbon, while in a pulverized or atomized state or in the form of vapor, to the action of heat and a current of air or oxidizing gas in fine jets; this treatment is stopped before the mass becomes carbonized, which occurs at 400 – 500° . The product is then treated with a solvent, such as benzene, petroleum, or tar oils, to remove the sol. portion, and the insol. residue is carbonized. The dissolved portion is distd. to recover the solvent

and is further subjected to the process described above, either alone or mixed with other hydrocarbons.

Brit., 6,445, Mar. 13, 1914. H. MILLIGAN. An adhesive paste is made from a powder comprizing ground manioc root well mixed with a non-poisonous, or substantially non-poisonous metallic chloride, such as $MgCl_2$, or $NaCl$, or both, and with or without a small quantity of maize flour, farina, or the like. For use, sufficient boiling H_2O is poured over the powder to give a paste of the proper consistence; this is followed by thorough stirring. When cool, the paste is ready for use.

Brit., 6,476, Mar. 14, 1914. J. L. BUCHANAN and E. B. MAXTED. Hydrogen is prepd. by passing a mixt. of CO , or gases containing CO , and steam over a catalyst consisting of an alkali ferrite which has been lixiviated so that a portion of the alkali is removed; the alkali ferrite may be prepd. by roasting Fe_2O_3 , as burnt pyrites, with Na_2CO_3 .

Brit., 6,477, Mar. 14, 1914. J. L. BUCHANAN and E. B. MAXTED. Hydrogen is prepd. by the interaction of CO and steam in the presence of a catalyst consisting of or containing a metallic couple; $Fe-Cu$ or $Fe-Ag$ couples are suitable. The catalyst may be made from lixiviated alkali ferrite, as described in 6,476 (*supra*), by reducing the Fe_2O_3 therein to the metallic state by H , etc., moistening with a soln. of $Cu(NO_3)_2$, and finally heating, preferably in a current of reducing gas, or washing, to remove nitrates. Gases containing CO may be used instead of CO itself.

Brit., 6,555, Mar. 14, 1914. OESTERREICHISCHE FILZKORKWERKE GES. In a process of obtaining spinning fibers, insulating material, and a substitute for cork flour from the barks of osiers, one-year old bark which has been stored in a moist and well aerated room is steamed in a vessel at 1 to 3 atms. pressure for 1 to 3 hrs., and then pickled in an alk. soap bath for 12 hrs. To sep. the long fibers, the material is then passed between fluted rollers to a hollander. After treatment, long fibers are lifted out by a rake and heated under pressure with a steam satd. with glycerol, after which they are dried. Bark and short fibers pass to the mixer, from which they are discharged to a trough having a sieve. Finer constituents passing through the sieve are ground to powder and used for filling linoleum. Coarser material is lifted out by dipper frames and pressed by means of a press into briquets, which may be used for insulating purposes.

Brit., 6,601, Mar. 16, 1914. P. KRETMANN. In reducing hard substances by preliminary crushing and fine grinding, the material is subjected to the action of an air current as it passes from the preliminary mill into the fine grinding-mill, whereby it is divided into 2 parts, the finer particles being carried into the fine mill by the air current, while the coarser particles are returned to the coarse mill.

Brit., 6,617, Mar. 16, 1914. J. LUTJENS. The supply of HNO_3 or other reagent supplying nitrous gases in the chamber or tower processes of mfg. sulfuric acid is controlled automatically by a thermometer in the chamber or tower, so as to maintain the reaction constant and thereby enable smaller chambers, etc., to be employed.

Brit., 6,739, Mar. 17, 1914. BRITISH THOMSON HOUSTON CO. (GEN. ELEC. CO.). Effecting reactions between gases by leading a gas through a heated porous tube and causing another gas to enter the tube through the porous wall thereof; the process is particularly applicable to obtaining N by passing air through the heated tube while a reducing-gas, e. g., H , is caused to enter through the porous wall. The tube may be continuously heated throughout the process from the initial source, or the heat liberated by the reaction may suffice to keep up the temp. In a form of app., a tube of alundum or other suitable material is contained in an air-tight casing and is provided with an elec. heating-coil of Pt , W , etc.; the end portions of the tube are made non-porous

by glazing or a cement coating, and the connections between the tube and casing are also rendered air-tight. The casing is filled with a suitable granular nonconducting material such as sand. The tube is heated to the desired temp., air is admitted by a pipe, and H from another pipe diffuses through the tube and mixes with the air; the resulting mixt. of N and water-vapor passes out by an outlet; the water-vapor may then be removed by cooling and the N purified from traces of H or O by passage over heated CuO and Cu.

Brit., 6,893, Mar. 18, 1914. C. CLAESSEN. Artificial mother-of-pearl. See Ger., 278,933 (C. A. 9, 1377).

Brit., 7,324, Mar. 23, 1914. B. BRAMWELL. Mixing liquids proportionally. The addition of one or more liquids to another which is passing through a Venturi pipe, *e. g.*, the addition of a chem. soln. to H_2O , is controlled by the difference of actual flow or wts. of liquid passed through orifices connected, respectively, upstream and at the throat of the Venturi pipe.

Brit., 7,419, Mar. 24, 1914. F. HAUSSER. In a process of absorbing nitrogenous gases in H_2O for the manuf. of nitric acid, interposing between each absorption chamber and the next an oxidation chamber in which the N oxide, which may be produced by the decompn. of HNO_2 , is made to travel through a very long course and is oxidized by the use of O without employing a catalyst.

Ger., 282,253, Sept. 19, 1913. GEWERKSCHAFT AMÉLIE. Mfg. hydrochloric acid and neutral potassium sulfate from $KHSO_4$ and KCl. The $NaHSO_4$ is first roasted with an excess of KCl to obtain $K_2SO_4-Na_2SO_4$. In the further treatment of the resulting mixt., in the wet way, with KCl, to obtain K_2SO_4 at a higher or lower temp., the concn. of the lye is controlled, with a view to securing a high % product, so that from 70 to 75 g. Na_2SO_4 seps. per 1000 cc. In order to obtain a higher yield of neutral K_2SO_4 , and to reduce the SO_4 -content of the resulting lyes, an excess of KCl is added. The mixt. resulting from the roasting of Na_2SO_4 with KCl is pretreated with the dil. liquors already obtained, instead of with H_2O , in order to reduce the amt. of the lye and more easily conc. it. In general, a temp. of 25-30° is sufficient. By repeated use of the lyes, these can be almost satd. with NaCl.

Ger., 282,370, Mar. 14, 1914. P. MÜLLER. Drying material spread out upon an elastic support which is expanded and allowed to contract as desired.

Ger., 282,566, Aug. 30, 1913. Addition to 271,246 (C. A. 8, 2465). G. SAUERBRY, MASCHINENFABRIK AKT.-GES. In the operation of app. for crystallizing salt solutions, especially K-salt solns., with the aid of air according to the principal process, the exhaust from the shafts is used as a measure of economy.

Ger., 282,609, Nov. 5, 1911. PERKINS GLUE CO. In mfg. wood size from starch by the action of alkali lye, the factors influencing the process, *i. e.*, the character of the starch, concn., time, temp., and manner of stirring, are so controlled with respect to each other that the product, which may be drawn out into threads, is suitable for coating the wood. If the starch is to be pretreated by hydrolytic or oxidizing substances, the initial material may be a moderately disintegrated product which does not dissolve clear in hot H_2O . Cassava may be employed as the starchy material. *E. g.*, into a glue kettle, provided with stirring app., are charged 275 liters H_2O ; the stirring app. is set in operation and then 100 kg. crude cassava meal (starch) are added in such manner that the meal and H_2O are completely and intimately mixed. After the meal has been added, stirring is continued for 30 min. Then, with continued stirring, a soln. of 10 kg. NaOH in 30 liters of H_2O is added, as slowly as possible in order to avoid bringing large amts. of the concd. alkali soln. into contact with the starch at one time. During the first stage of this treatment, the starch undergoes a change

analogous somewhat to the so-called breaking down effected by the pretreatment with oxidizing or hydrolyzing agents. After all the alkali has been added, the mixt. is ready for use as wood size. The desired end point of the alkali treatment is recognized in that the stringy product is also suitable for spreading. To stabilize the mass, a small addition of NaOH, 0.5-2%, is made at the end of the operation. Potato starch and corn flour are also suitable for this process.

Ger., 282,701, Dec. 7, 1913. EHRICH & GRAETZ and E. PODSZUS. Mfg. pure or practically pure boron nitride. Heretofore the production of BN in a sufficiently pure state and in sufficiently large quantities has failed, principally because in the removal of foreign matter chemically, the BN suffered reversion to H_2BO_3 . In this process there are mixed with the reaction mass substances, such, *e. g.*, as C or BN, which neither sinter nor frit and which can be removed by a gas reaction; these are added to the B_2O_3 in such amts. that sintering does not occur to any great extent. The mixt. of anhydride and added materials is ground in a ball mill. The ground mass is subjected to the action of NH_3 while maintaining the temp. above 1000° , since at lower temps. the NH_3 acts very sluggishly. Preferably a temp. of about 1800° is employed because at that temp. the trioxide volatilizes and reacts more rapidly. In case the mixt. bakes together during the reaction, which indicates that not all the trioxide has been decomposed, the mixt. can be reground and again treated with NH_3 . This operation can be repeated as often as necessary, the BN already formed serving as an admixt. advantageous to the process. If coal be used as the added substance, it can be removed, during or after the reaction, by the reaction with NH_3 , in the form of CN compds. Some H_2O may be admitted with the NH_3 ; the resulting H_2BO_3 is volatilized at a sufficiently high temp., and is reconverted by means of NH_3 into BN. At the same time, the C hastens the reduction of the trioxide. If BN be added instead of C, the process can be made continuous, since definite amts. of B_2O_3 can be added from time to time, and the operation repeated. If the product still contains acid, it is subjected to a rectification in a current of NH_3 at a temp. sufficiently high to volatilize the trioxide and ppt. the B as BN. If C is not used, a tube of BN is used. The product is so pure that at the highest attainable temps. no trace of baking together is apparent, and no B_2O_3 or Ca compds. are given off.

Ger., 282,745, May 14, 1913. R. WUSSOW. Separating gases of different properties from gas mixts., by means of diffusion and absorption, simultaneously, with the employment of a pressure chamber in which tubes are fitted which are made of a material permeable to one gas constituent, while the space between the tubes is filled with an absorbent for another constituent. The gas is introduced preferably under pressure. *E. g.*, if a mixt. of water-gas containing 67% H_2 and 33% CO_2 is to be sepd., a porous partition (of clay) may be used, the space between the tubes being filled with beechwood charcoal. After the first diffusion the mixt. has been found to consist of 83% H_2 and 17% CO_2 .

Ger., 282,746, Nov. 12, 1913. CHEM. FABRIK GRIESHEIM-ELEKTRON. In the manuf. of solid high grade calcium hypochlorite, employing a mixt. which contains all the CaO required for the formation of the hypochlorite, with a relatively small amt. of H_2O , and introducing sufficient Cl for the production of the hypochlorite. The H_2O content of the hydrate is so calcd. that upon chlorinating only the hypochlorite seps. out; the chlorite formed at the same time remains in soln. The process is carried out continuously at such temps. that the intermediate product does not sep. The Cl can be conducted, under pressure, upon or over the reaction mixt., with stirring, shaking, or the like. If, *e. g.*, a lime slurry containing for 1 part CaO at the most 2 parts H_2O is used, the mere passage of the required amt. of Cl leads to the production, with a smooth progress of the reaction, of the desired hypochlorite, which crystallizes

spontaneously from the highly conc. soln. Practically the temp. is not reduced while sufficient lime is present to prevent the decompn. of the hypochlorite formed. As the pressure is increased, the temp. is raised, since with increased pressure the absorption of the Cl is increased and consequently the temp. of the reaction. By maintaining suitable reaction temps., the basic intermediate product does not cause decompn. If, however, the temp. falls, as by interruption of the process, the basic compd. seps. out in considerable amt. In such cases the decompn. of the pptd. basic compd., by further introduction of Cl, proceeds very difficultly and slowly. Good results are secured by operating at a chlorination temp. of 35-45° and under a pressure of about 500 mm. of H₂O. Towards the end of the chlorination the temp. is preferably reduced to 25° in order to prevent a decompn. of the formed hypochlorite, the pressure at the same time being increased to 2000 mm. H₂O. The chlorination is then completed within 1 to 2 hrs.

Ger., 282,747, Jan. 10, 1913. E. HARTMANN (v. E. HARTMANN & F. BENKER). In the manuf. of sulfuric acid by the chamber process, increasing the durability of the tower system by interposing between the towers which serve as the reaction chambers and those which serve as Gay-Lussac towers, a tower which is provided with a filling and sprayed with H₂SO₄ of ordinary strength. This interposed tower provides added opportunity for the condensation of the acid spray carried over with the current of gas, especially when operating with a rapid current of gas or when forcing the plant. The condensing action of the tower can be increased materially by spraying with ordinary H₂SO₄. HNO₃ is saved and the production of the plant is increased, whether the tower system is filled wholly or partly with coke or prism-stones, Glover rings, or the like. In certain circumstances the tower may be sprayed with nitrososulfuric acid in order to oxidize the last traces of SO₂.

Ger., 282,748, Oct. 23, 1913. E. PODSZUS. In the manuf. of strong articles from nitrides, especially from the nitrides of B and Ti, the easily sintered compds. of the initial materials, such as the oxides, especially B₂O₃, TiO₂, are formed into solid bodies, then sintered, and converted into the nitrides by strong heating in an atm. of NH₃ or the like. Only a portion of the initial materials need be of sintering material, while the rest may be nitride. The oxide can be formed during the operation by a partial conversion of the nitride. The nitrides of B and Ti are formed preferably with organic binders, and the binder is burned out in contact with the air, with partial oxidation. BN products can be satd. with molten B₂O₃ or a soln. of H₃BO₃ and ignited in a current of NH₃, and if necessary this process may be repeated. Before application in the process, TiO₂ is ignited or melted. The products serve for all purposes in which high temps. are required and a reducing atm. prevails. The BN treated in the manner specified dissociates only at 2000° or over, and sublimates above this temp. in a current of H₂, while in a current of NH₃ and N it resists temps. up to 3000°. It is especially suitable for use as melting crucibles for metals, since even boiling alkali metals have no action upon it. Articles of Ti nitride are made in an analogous manner by grinding a burned or molten oxide as finely as possible, shaping the mass with an organic binder, and burning in an oxidizing fire or directly in NH₃. At first, the oxide sinters and then is converted into the nitride. If a metal, such as W, is to be incorporated, this is mixed with the oxide and the whole mass is burned in a current of NH₃.

Ger., 282,750, Feb. 26, 1914. Addition to 238,255 (C. A. 6, 1556). GEHR. BURGDORF. Constructional details of an app. for dissolving potassium salts.

Ger., 282,776, Sept. 25, 1913. E. MÜLLER. Fire kindler.

Ger., 282,849, Dec. 4, 1913. BADISCHE. Obtaining hydrogen by the catalytic double decompn. of CO or gases containing CO with steam, with the employment of

Ni as contact metal. When CO and steam, in the presence of Ni, are converted into CO_2 and H_2 , an undesired by-product (CH_4) is formed. To prevent the formation of CH_4 , there may be employed mixed contact masses, consisting of an excess of Fe or its oxides with the Ni or its oxides. Other elements or their compds., which have active properties, are added advantageously. The specified contact masses, even at low temps., effect a rapid and extensive decompn., and are to be preferred to Ni because of their stability and slight sensitiveness to accidental increases in temp. and to impurities in the gas mixt. The contact mass is applied preferably in the form of porous pieces. *E. g.*, a suitable mass is obtained by pptg. a mixt. of 40 parts $\text{Fe}(\text{NO}_3)_3$, 5 parts $\text{Ni}(\text{NO}_3)_2$, and 5 parts $\text{Cr}(\text{NO}_3)_3$ (all free from Cl), in soln., with K_2CO_3 , and thoroughly washing. The mass is then formed, dried, and a water-gas-steam mixt. is conducted over it at 400–500°. The amt. of Ni can be increased or diminished. In a modification, the principal portion of the CO can be removed with a suitable catalyzer at 500–600° and the gas, while still hot, is freed from H_2S by passage over Cu, or the like, and then, with the addition of steam, it is conducted over the new contact mass at 350–400°.

Ger., 282,891, Feb. 14, 1914. DIEDRICH P. SCHRÖDER. In mfg. soot from bituminous coals of all kinds, such as brown coal, the coal is first extd. with H_2O in drums, mortars, stamping mills, or the like. The constituents dissolving out are removed by means of H_2O in filter presses or extg. app. After the addition of very dil. NaOH or KOH soln. the coal is ground further, until it is reduced to the moisture content of bone black. The coal is then stirred up with an equal or greater amt. of 10–30% alkali soln., and worked further in disintegrators, or the like. Rotary friction app. are preferred. By this treatment the bituminous portions are dissolved, and an extremely fine, mol. C of exceptional covering power, is obtained. The mixt. is then freed from liquid constituents in filter presses, and the residual alkali is washed out, whereupon the mass is dried. The expressed or dissolved bituminous constituents are used as a caustic agent. Any residual impurities, such as bitumen, oxides, or the like, remaining in the black product, can be removed by repeated grinding with H_2SO_4 , HF or the like. The acid is then washed out and the H_2O is removed by heating. In removing the last trace of H_2O some alc. is added, or the mass is extd. with alc., whereby an exceptionally fine black product is obtained. Instead of treating the crude coal with NaOH, or the like, Na_2CO_3 , NaCl, or Na_2SO_4 may be used, in such manner that the mass is subjected to electrolysis, when the Na seps. on the cathode and at once forms NaOH with H_2O . The mixt. must be maintained in constant motion by a stirring app.

Ger., 282,913, Aug. 5, 1913. C. FRHR. VON GIRSEWALD. Mfg. hydrofluoric acid by prepg. a mixt. of fluorspar and H_2SO_4 in the usual manner and heating the mixt while at the same time introducing superheated steam. The amt. of steam added is detd. first by the concn. of the acid employed, and second according to the strength of HF desired. Inasmuch as the added H_2O is for the greater part distd. over, correspondingly less H_2O is placed in the receiver than heretofore. For highly concd. acid, practically no H_2O is placed in the receiver. This process effects a saving in fuel. By the addition of steam, the mixt. of acid and fluorspar is more intimately mixed and the heat applied is more uniformly distributed. By dilg. the concd. acid with H_2O , a considerable amt. of heat is liberated; this is completely utilized. The steam passing over with the acid aids in the expulsion of the latter.

Ger., 282,952, Mar. 15, 1913. BAYER & CO. Purifying rock salt by repeatedly treating it with a soln. satd. as to NaCl and free from H_2SO_4 or its salts, until the NaCl sepd. from the ext. in the known manner has attained the desired purity. The temp. may be varied between wide limits, up to the b. p. The salt liquor from the extn. is freed from the lime and Mg salts taken up, and is then returned for further extn.

of crude salt. *E. g.*, 1000 kg. crude ground rock salt are digested at 50–80° in a suitable app. with a soln. satd. with pure NaCl and acidified with HCl, until the suspended salt has acquired the desired degree of purity. The purified salt is then sepd. from the extn. soln. in the usual manner by suction, centrifugation, or the like, or it is covered with a salt soln. and used either in a moist state or after drying. *E. g.*, by this process, from a crude rock salt which according to analysis contains 1.21% insol. matter and 0.497% impurities precipitable by means of Na_2CO_3 , may be obtained a purified NaCl which contains only 0.104% insol. and 0.0046% precipitable impurities.

Ger., 282,953, Aug. 19, 1913. R. HOMBURG. Making transfers on stone or metal plates. H. uses a transfer paper coated with a mixt. of albumin and adhesive, CaCl_2 and glycerol, a transfer color consisting, to about one-half, of soap, wax and fatty substances, and the rest of Peru balsam, and a cleaning mixt. consisting in the main of turpentine oil, asphalt, wax, and Peru balsam.

Ger., 283,026, Apr. 17, 1913. W. JANENSCH. Solution or extraction of substances, especially those of a granular, fibrous, or like character, by means of a current of liquid or air under pressure directed into the lowest portion of a container cone-shaped at the bottom. The current of liquid or air, under pressure, is directed back and forth, and the efficiency of the app. is increased according to the force with which the solid matter, which is drawn up into the tube, is thrown out when the current is reversed. This projected material also acts as a piston, aiding soln. Furthermore, the suction produced when the material is drawn up into the tube, causes an active circulation, which greatly assists soln. Also, the impact of the projected matter aids in the crushing of such material as beet root cuttings. As illustrated, the current under pressure is delivered through the tube *b* into the deepest portion of the vessel *a*, where the material *c* under treatment collects, and forces this material upwards, while the material lying along the sides of the vessel *a* slips down and is subjected to the action of the current. According as pressure or suction is used, the vessel may be open or closed. *d* is an exit tube.

Ger., 283,065, June 10, 1914. N. KRANTZ. In a sulfuric acid chamber, the floor of the chamber is constructed so that a special cooling of the reaction gases is effected. It is preferably of a step-like construction, and the several steps are provided for drains for the acid. Various modifications are specified.

Ger., 283,096, Nov. 18, 1913. CHEM. FABRIK BUCKAU. Utilizing magnesium chloride waste liquors of the potash industry by adding H_2SO_4 and heating to the boiling temp. All the Cl is expelled as HCl and is taken up in the usual manner. *E. g.*, the waste liquors are treated in a Pb, cast Fe, clay, or like vessel, provided with a distn. mounting, with the required amt. of H_2SO_4 of 60° Bé., or even with more dil. acid, and the mixt. is maintained at the boiling temp. by direct firing or by means of steam. The HCl passing over is condensed. The boiling may be continued until MgSO_4 remains as a cryst. powder, which may be utilized in the usual manner.

Ger., 283,104, July 17, 1913. Addition to 281,831 (*C. A.* 9, 1981). C. BREITHAUP and W. ZIERVOGEL. Detailed procedure in the separation of salts from solutions by the action of a current of air, according to the principal patent.

Ger., 283,160, Oct. 31, 1913. J. PINTSCH, AKT.-Ges. In a hydrogen generator operating according to the so-called Fe-contact process, water-gas and air are conducted into a shaft filled with Fe_2O_3 to preheat and reduce the oxide, and then steam is introduced, whereupon the O combines with the Fe, while the H is liberated. The water-gas so used is preheated in a preheating system wherein the heat from the heating period of the generator is utilized. Cf. C. A. 9, 1376.

Ger., 283,161, Feb. 6, 1913. E. COLLETT. Oxidation of sulfite, especially of $(\text{NH}_4)_2\text{SO}_3$, to sulfate, in soln. by means of gases containing O.

Ger., 283,182, Apr. 28, 1914. W. HUBMANN. Obtaining potassium chloride. Many crude salt solns. of potash works contain large amts. of fine slimes which upon clarification settle with difficulty, requiring a long time. During the cooling incident to this clarification, a large amt. of the KCl seps. and is difficult to recover. By the present process the crude soln. is conducted through a sedimenting box in which kieserite and entrained particles are sepd. The soln., after some diln., is transferred to the crystg. box. After several days the slime has settled out completely, and the first product is crystd. out. The mixt. of crystd. salt and slime, after pouring off the mother liquor, is heaped up in the box to free the mixt. as completely as possible from adherent mother liquor. The slimy salt is treated then, in suitable app., in counter-current with end lyes with the aid of air blast, and by vigorous agitation of the salt and the end lye the slime is sepd. from the KCl. The fine slimes are taken up by the strongly agitated end lyes, and sepd. in this manner from the salt. Since the end lyes are not in condition to dissolve the KCl, there is no loss of the latter.

Ger., 283,302, Apr. 2, 1914. V. KLOPPER. Solution or softening of vegetable albumin, e. g., flour paste, by means of a treatment with Turkey red oil. E. g., 1 kg. fresh material, after gentle warming, is worked up with 500 g. Turkey red oil, whereupon it dissolves to a transparent, gelatinous mass.

Ger., 283,338, Jan. 24, 1914. Addition to 261,151 (C. A. 7, 3211). H. SCHROER. In mfg. a cleaning liquid for glass surfaces, such as glass sky-lights, windows, arc lamp globes, and the like, instead of the H_2SO_4 in the liquid of the principal patent, which only loosens the dirt after a long time, in this process hydrofluosilicic acid is used. A cleaning liquid which consists of the aq. exts. of quillai, or the like, H_2SiF_6 and Cu salts, has the effect of permitting the removal of all dirt after application to the surface. E. g., 1.5 kg. quillai bark is extd. with H_2O , and the cooled ext. is made up with H_2O and the prepared acid (20 liters HF of 70-75% and 2 kg. SiO_2), together with a soln. of 20 g. CuSO_4 to 100 liters.

Ger., 283,347, Aug. 31, 1912. E. R. BESEMVELDER. In a process of evaporating or drying liquids, the liquids are subjected to the action of flowing vapors of other liquids, excepting steam, whereby a vapor mixt. is obtained with b. p. lower than the temp. of the liquid under treatment. In this manner liquids sensitive to heat and readily decomposed can be dried without excessive heat. The process is especially applicable in milk pasteurization. Suitable liquid vapors are benzine, benzene, alc., ether, toluene, turpentine oil, CCl_4 , MeOH, $\text{C}_2\text{H}_5\text{Cl}$, C_2HCl_3 , nitrobenzene, EtBr, Et benzoate, naphthalene, CS_2 , etc.. The vapor chosen for a particular liquid should be that of a liquid which upon condensation does not mix with the condensate of the liquid under treatment. The vapor mixt. is, therefore, condensed, and the condensate is sepd. according to sp. gr., the drying liquid being returned to the process. The liquid under treatment is atomized into the current of drying vapor. According to the nature of the liquid under treatment, the operation may be started with a vapor from a liquid of a lower b. p., and concluded with the vapor of a higher b. liquid, or *vice versa*. A mixt. of different liquid vapors may be used in conjunction, e. g., ether and benzene

or ether and C_2HCl_4 . The progressive drying process may be used for drying albumin, at first employing vapors of benzine b. at about 85° , and finally ether vapor of 35° . The completely dried albumin loses the odor of ether readily when exposed to the air.

Ger., 283,445, Feb. 24, 1914. J. BREHNS. Employing C suspended in a liquid in the separation of gas-, vapor-, or gas-vapor-mixtures by absorption. Expts. have shown that wood charcoal or blood charcoal slimes, *i. e.*, a suspension in H_2O of finely divided C of the kinds specified absorb, under like conditions of pressure, 8 times as much H_2S and CO_2 as does H_2O alone. The gas absorbed in the slime is approx. proportional to the content of suspended C, and is dependent otherwise to a great extent upon the pressure of the gas absorbed in the H_2O . The slime yields the absorbed gas under vacuum, to a great extent. By protracted heating of the slime in the H_2O bath, the gas is almost completely eliminated. A slime of 40% linden charcoal or blood carbon and 60% H_2O (by wt.) may be prepared readily by adding the C to hot H_2O , and heating the mixt. for 1-2 hrs. at 97° . The product has a drop-wise fluidity, permits the C to settle very slowly, and has a sp. gr. of 1.17. If, *e. g.*, crude coal gas is to be freed from H_2S by means of such a slime, the circulating slime is allowed to flow down, in an Fe cylinder, over a wood grating, while the gas current is directed against the slime from below upwards. The regeneration of the slime is effected by heating, and upon return to the process it is cooled on the countercurrent principle, by means of the cold slimes flowing to the regenerator. Pure S can be obtained readily from the H_2S thus obtained, by the C. F. Clauss process. The H_2S -slime may also be conducted, for regeneration, to a second tower or cylinder, wherein a current of fresh air rises and carries the H_2S with it. The H_2S -laden air may be conducted into any burning mass. If the mixt. of air and H_2S is to be employed for the catalytic manuf. of SO_2 , the H_2S -content is increased by passing the air through the second tower and drawing it off at the top by means of a vacuum pump. The rising air has then a tension less than 760 mm. Hg, but takes out the same amt. of H_2S from the slime. Also for sepg. the CO_2 from the flue gases from steam boilers or from the exhaust from gas engines, the slime is especially suited. In the same manner coal gas can be freed from small admixt. of aldehyde vapor, and pure aldehyde can thereafter be distilled off.

Ger., 283,501, May 15, 1912. BADISCHE. Mfg. hydrogen. See Fr., 453,077 (C. A. 7, 4050).

Ger., 283,536, July 29, 1913. A. REICH. Manuf. of alkali hydroxide. Expts. have demonstrated the fact that upon igniting a mixt. of an alk.-earth carbonate with alkali silicofluoride or alkali fluoroborate, the dissociation tension of the CO_2 increases to such a degree that even at a dark red heat (a temp. below the temp. of decompn. of the silicofluorides) all the CO_2 is driven off and a reaction is effected in the sense of the equation— $K_2SiF_6 + 4BaCO_3 = 4CO_2 + 3BaF_2 \cdot BaSiO_3 + K_2O$. If sufficient alk.-earth carbonate be employed, all of the alkali in the silicofluoride is obtained as hydroxide, upon soln. of the melt in H_2O , while the alk.-earth metal remains undissolved as fluosilicate. Apart from the economy, due to the employment of the carbonate instead of the oxide, there is advantage in the employment of the most effective of the carbonates, $BaCO_3$. This is especially desirable in the subsequent regeneration of the hydrofluosilicic acid from the resulting Ba fluosilicate by means of H_2SO_4 , inasmuch as the almost insol. $BaSO_4$ seps. out completely and may be readily sepd. from the silicic acid; this can be accomplished only incompletely with $CaSO_4$.

Ger., 283,601, July 26, 1914. J. PINTSCH, H. STRACHE and H. HILLER. Converting H_2S from distn. gases into sulfuric acid or its salts. Heretofore, H_2S could be oxidized by ferric salts only to S. Expts. have shown that upon conducting gases containing H_2S into a hot $Fe_2(SO_4)_3$ soln. strongly acid with H_2SO_4 , with alternate or simultaneous regeneration of the resulting $FeSO_4$ with air or O, an oxidation of the

H₂S to H₂SO₄ is effected without sepn. of S. By air or O blast, the ferric salt is regenerated and the S sepd. at first is dissolved, in the heat, in the H₂SO₄, with its partial reduction to SO₂ according to the equation $2\text{H}_2\text{SO}_4 + \text{S} + \text{H}_2\text{O} = 3\text{H}_2\text{SO}_3$. The SO₂ reduces the ferric ion and is itself oxidized to H₂SO₄. These 2 reactions proceed simultaneously. The H₂SO₄ obtained in this manner contains Fe and can be used as such or for combination with NH₃, whereby, after neutralization, any remaining FeS can be sepd. from the (NH₄)₂SO₄. The regeneration of the FeS results upon return to the oxidation soln.

Ger., 283,618, July 15, 1913. FARBW. v. M. L. & B. Mfg. sulfates from the corresponding sulfites by oxidation by means of O or air, operating in very dil. solns., in the absence of negative catalyzer. Concd. solns., under the same conditions, are converted only slowly into sulfate. The reaction is hastened, under such conditions, by operating in the presence of Se and Te (in the form of their elements or their compds.) as catalyzers. E. g., a concd. aq. soln. of (NH₄)₂CO₃ is converted into sulfate by means of O of the air, if necessary ozone, in the presence of a small amt. of Se in the elementary or combined form, in a much shorter time than when operating without the addition of Se. The O or the air is employed preferably in the finest state of subdivision, and in excess. Heat and increased pressure favor the reaction.

Ger., 283,746, Oct. 25, 1913. GUBINOL-GES. M. B. H. Sheet metal foil for imprinting, provided with a readily sol. surface film of thin mirror-like material, such as stanniol, Al, cellite, cellophane, and the like. This material is provided with the adhesive and upon this the foil is laid. As adhesive may be employed any waxy substance, such as paraffin or fat, which m. readily in the heat without becoming glutinous.

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

American clay for American potteries. A. V. BLEININGER. *Commerce Repts.* No. 165, 258-60 (1915).—Until importation was disturbed by the war, European clays were used exclusively for certain ceramic products. As yet no single American clay has been found to be an entirely satisfactory substitute, but mixts. of American with European clays give good results and it is predicted that soon there will be found an American clay or combinations of American clays that will replace foreign clays altogether. Some important sources of clay are mentioned. E. H.

Preliminary report on the clay and shale deposits of the Province of Quebec. J. KEELER. Canada Dept. of Mines, *Mem.* 64, 196 pp. (1915).—The clays are described according to the geological age in which they were laid down. The Pleistocene clay is remarkably uniform in its chem. comp. over all the regions investigated. The effect of varying quantities of sand on the strength of the burned clay was observed. It was found that the addition of 25% sand reduces the strength of the body nearly one-half while with 50% sand there is only about one-quarter the strength of the all-clay cube. The addition of sand has the effect of reducing the quantity of water required for tempering and reducing the shrinkages. It makes the clay easier to work, easier to burn, easier to dry. Most of the Pleistocene clays of the St. Lawrence valley have a tendency to crack while drying and produce a sticky and pasty type of plasticity, causing them to adhere to metals and making them hard to work or mold. They have an excessive drying shrinkage also. These defects are caused by extreme fineness of grain and by large percentage of colloidal material in the deposits. Such clays can be made workable by preheating. The new ante-fired process of making brick was tried. In this the clay is burned in heaps by wood or coal as it comes from the bank and is ground fine enough to pass through a 12-mesh sieve. The ground clay is then

moistened, mixed with 5-6% of hydrated lime, pressed into brick shapes and then hardened in cylinders under a steam pressure of 100-140 lbs. per sq. in. for 8 hrs. Brick made by this method appeared to be as strong and to withstand the freezing test as well as a medium grade of soft mud brick but they do not have the quality of toughness, as the corners and ends were rather crumbly. Sand-lime brick are made from lime and sand-stone. The reaction upon which this industry is based depends upon the fact that under the action of high pressure steam, the lime attacks the particles of sand and a chem. comp. of water, lime and sand is produced which forms a strong bond between the larger particles of sand. The addition of 2% quicklime to the clay in the manufacture of clay wares destroyed the stickiness of the clay and made it much easier to work. Chapters on drain tile manufacture, clay-working industry, sand-lime brick, the origin and general properties and kinds of clay and the field examination and testing of clays are included. Several samples collected were submitted to tests for working qualities, shrinkage and burning.

Plan to manufacture cement in Brazil. ROBERT FRASER, JR. *Commerce Repts.* No. 167, 295(1915).—It is proposed to manuf. cement from sea shells. E. H.

An air analyzer for determining the fineness of portland cement. J. C. PEARSON AND W. H. SLIGH. *J. Frank. Inst.* 179, 712-4(1915).—Description of a device for permitting the introduction of an unretarded air stream into a conical bulb, a sep. chamber of considerable height which permits no lodgment of either fine or coarse particles, a tapping device to minimize adherence of fine dust and a collector operating in conjunction with the sepg. chamber. The error in estg. the quantity of any desired fraction from the mechanical analysis curve will not exceed 1.5%. A. J. PHILLIPS.

The significance of reactions in the solid state for the burning of limestone. K. ENDELL. *Tonind. Ztg.* 39, 73, 85-6, 107-8(1915).—E. holds that the slow slaking of dead-burned CaO is due to the growth of the CaO grains during burning. He reviews the work of Cobb (*C. A.* 4, 1092 and succeeding articles) to show that crystal growth and reactions are possible in the solid state. W. L. BADGER.

The decomposition of cement mortars by water. CHEM. LAB. FÜR TONINDUSTRIE. *Tonind. Ztg.* 39, 215-6(1915).—Compression test pieces were made of 1:9, 1:4 and 1:2 mortars. These were kept 7 days in a moist closet, then stored by different methods, and tested at 1, 3, 6, and 9 mos. Those stored under still water were used as standards. A set on which water was allowed to trickle developed stalactites of CaO on the leaner mortars with consequent loss in strength. A set immersed in flowing water also decreased in strength in the leaner mortars; while a set half immersed in running water was almost equal to the control. A set which had been made by half filling the forms, waiting 24 hrs., and then finishing, showed considerable loss in CaO at the joint. W. L. BADGER.

Fire test on reinforced concrete. ANON. *Cement Eng. News* 26, 73(1914).—A 5-ft. cubical tank 3 in. thick with ribbed reinforcing was made from 5 pts. cement, 12 sand and 1 lime paste; it was aged 29 days and 160 gals. kerosene fired in it. The fire burned 2.75 hrs., a max. deflection of $\frac{3}{8}$ in. being noted. While warm, the tank was filled to within 18 in. of the top and the walls retained their strength against the H₂O pressure. A. J. PHILLIPS.

Investigation of the durability of cement drain tile in alkali soils. R. J. WIG, G. M. WILLIAMS, et al. Bureau of Standards, *Technologic Paper* No. 44, 56 pp. (1915); *J. Frank. Inst.* 179, 354-6(1915).—Conclusions drawn from 1 yr. field tests of 16 types of drain tile made in one plant, together with soil and H₂O analyses are: that mixtures not leaner than 1-3 are unaffected structurally within 1 yr. in operating drains in very concd. alkali soils. Not leaner than 1-3 mix should be used in localities where alkali is found in concns. similar to that in experimental drains at Grand Junc., Col., Montrose, Col. and Garland, Wyo. 1-4 mixts were unaffected within 1 yr., in soils similar to those of Fort Shaw Mont., Sunnyside, Wash., Yuma, Ariz. and Roswell, N. M. A. J. PHILLIPS.

Experimental concrete roads. J. T. VOSHELL. *Cement Eng. News* 27, 91-2 (1915).—Exam. of experimental roads laid in Montgomery Co., Maryland, in 1912, of bituminous concrete, cement concrete and brick shows apparently no difference in the plain and oil concrete sections. Where bituminous materials were used as coatings, the refined water gas tars are best and the coal tars next; the asphalt coatings did not adhere well to the concrete surface and many bare spots remain.

A. J. PHILLIPS.

Cracking in concrete roads. A. N. JOHNSON. *Cement Eng. News* 26, 247-8 (1914).—Wet concrete for roads shrinks for 24 hrs. from drainage and then expands during the next 3-4 months due to chem. action. Expts. made by Spackman indicate that the addition of 10-15% hydrated lime reduced cracks and eliminated the formation of holes and soft spots. $\text{Ca}(\text{OH})_2$ causes the mortar to hold H_2O and prevents segregation of the cement from the sand.

A. J. PHILLIPS.

U. S., 1,146,532, July 13. A. C. SPENCER. Natural cement rocks containing potash are disintegrated and heated to a temp. just below their fusing point until at least a portion of the potash is volatilized and recovered and the residue is then pressed into building blocks.

U. S., 1,147,635, July 20. H. S. LOUD. Treating wood with preservative liquids by drenching the surface of the wood with the liquid and subjecting to air under pressure which is progressively increased during the process.

Brit., 6,573, Mar. 16, 1914. TURNER BROS. and H. R. TURNER. A fire-resisting block especially applicable for the bulkheads of ships consists, in one form, of a series of layers of corrugated sheets of asbestos attached to flat sheets faced with a protecting slab of asbestos cement. The corrugated sheets may be of the form described in 23,621, 1910, and may be formed of any suitable insulating material, such as MgO or fossil-meal. The protecting slab may be corrugated or may be reinforced with metal as described in 14,266, 1913 (C. A. 9, 136).

Brit., 7,061, Mar. 20, 1914. A. ANKER. In a process of slaking lime or other mortar material, the material is fed from a hopper, *b*, through a valved sluice chamber and falls vertically downwards through a chamber, *e*, surrounded by an outer chamber, *f*. The inner chamber is connected with the outer one by an open top, or by perforations in its sides, or both. When perforations are provided, surfaces *g* may be arranged so as to prevent lime passing into the outer chamber. Similar inclined surfaces may be provided on a member arranged centrally in the inner chamber, which may also be provided with distributing steam-pipes or with sieve-like members allowing the entrance of steam but preventing the escape of the lime. Steam is admitted by a pipe, *i*, and condensed water is withdrawn at *k*. The slaked material is discharged through a valved sluice chamber, *h*. The material may be moistened before feeding to the slaking-chamber, and if enough water is present, moist or dry hot air may be admitted to the slaking-chamber instead of steam. Steam evolved in the sluice chamber

at the top may be led off by a pipe, *m*, through a coil, *n*, for heating the lime in the hopper.

Aust., 1,892, Mar. 2, 1911. MAXIMILIAN MAYERL, JR. In a process of impregnating and preserving wood, the wood articles are lightly coated with tar oil, or the like, which is mixed with a readily combustible substance, such as alc., benzine, or the like, in such proportion that upon burning this admixt., neither the other constituent of the mixt. nor the wood is ignited or destroyed. The burning off of this readily combustible constituent burns in the other constituent.

Aust., 9,210, Oct. 28, 1913. F. HELLER. In the manuf. of wood impregnating agents, with the use of colloids, the soln. of a fungus poison is mixed hot with a colloid in the sol. condition, so that upon complete drying the colloid seps. in the wood as a gel and retains upon its entire surface the fungus poison while at the same time preventing extn. by stopping up the pores.

Ger., 281,842, Mar. 14, 1914. GRÜBENHOLZIMPRÄGNIERUNG, G. M. B. H. In the application of mercuric chloride as a disinfecting agent and preservative for wood, soaking of grain, and the like, the chloride is decomposed readily by metals, which detracts from its efficiency and at the same time corrodes the metals. To overcome these objections, alkali nitrite is added, an addition of 2% alkali nitrite to a 0.1-0.2% HgCl_2 soln. being sufficient to prevent the action of the metal parts of instruments used for disinfecting purposes. Sol. salts which enhance the preservative action may be added, provided these have no decomposing action on alkali nitrite. *E. g.*, MgSO_4 may be added to increase the fireproof qualities of impregnated wood. The action of alkali nitrite appears to be physical, without chem. altering the HgCl_2 .

Ger., 282,696, Jan. 8, 1914. A. ANKER. Process of slaking lime. See Fr., 456,330 (*C. A.* 8, 2793).

Ger., 282,777, Mar. 13, 1912. RÜTGERSWERKE AKT.-GES. In a process of impregnating freshly cut or incompletely dried wood, the wood is subjected to the action of a vacuum while heated in the impregnating liquid, a low vacuum being maintained const. in the known manner and while the impregnating liquid is being drawn off, and then the impregnation proper is carried out with limited amts. of tar oil according to the usual practice. After a sufficient amt. of H_2O has been driven out of the wood by heating in the impregnating oil, as detd. by measuring the H_2O vaporized, the impregnating oil is drawn off without suspending the vacuum, which is not allowed to exceed 40 cm. of Hg. In this manner the oil is prevented from entering the wood. After the removal of the oil an economical process, such as those specified in 138,933 or 212,911, is employed to effect the impregnation with tar oil.

Ger., 282,907, June 10, 1913. Addition to 261,680 (*C. A.* 7, 3654). HOCHOFEN-SCHWEMMSTEIN-SYNDIKAT, G. M. B. H. In the manuf. of light weight stone, slags from generators, from the cupola furnace, from Cu smelting, also from rock materials which in the natural state are not suitable, are covered with thin mortar and left until this coating hardens; then the product, by admixt. with a binder, is converted into a mass suitable for the manuf. of the stone.

The solid fuels in 1914. W. BERTELSMANN. Waidmannslust. *Chem. Ztg.* 39, 497-9(1915).—A review, with bibliography.

J. H. MOORE.

Coal fields of Manitoba, Saskatchewan, Alberta and Eastern British Columbia.

D. B. DOWLING. Canada Dept. of Mines, *Mem.* 53, 122 pp.(1915).—The report is a concise statement of the area and probable contents of the various coal fields of the middle portion of Canada. References to various reports giving details of thickness of seams and character of enclosing rocks are given. The character of the coal is treated in some detail. Forty pages are devoted to tables of analyses of coals, and for purpose of comparison, other analyses of North American and foreign coals are included.

R. L. SIBLEY.

The significance of chemical control in operating the purifiers. C. J. H. MADSEN. Copenhagen. *J. Gasbel.* 58, 234-7(1915).—By making detns. of H_2S daily at the inlet and outlet of each purifier a definite indication is given as to just what each is doing, and as to when renewals are necessary. Several sets of analyses are given and interpreted. In 1908-9, using a "counter-current" system, and changing the order of the boxes every 2 days, there were 74 renewals in 8 months (April-Nov.), with a production of 580 million cu. ft. In 1912-3 a system was employed whereby each day the last box of the day before was made the first: *e. g.*, 1-2-3-4, 4-1-2-3, 3-4-1-2, etc. By simultaneously introducing air, the last box was regenerated. With this method there were 44 changes in the same time, with a production of about the same quantity of gas. In 1914 with chem. control and a production of 630 million cu. ft., only 16 renewals were made. A buret for titrating a sample of gas with I is described.

W. L. BADGER.

Coke-oven accidents in the United States during the calendar years 1913 and 1914.

ALBERT H. FAY. Bur. of Mines, *Tech. Paper*, 118, 16 pp.(1915).—Statistics. During this period 91 men were killed at coke ovens in the U. S., 644 were seriously injured and 4,059 slightly injured.

Ger., 282,651, Dec. 19, 1912. **MASCHINENFABRIK BAUM, AKT.-GES.** Machine for drying fine coal.

Ger., 282,673, Mar. 1, 1914. **K. BRUNNER and C. H. WECK.** Movable grate adapted to move from the fire-bridge towards the stoker who shovels the fuel onto the portion of the grate next to the fire-bridge.

Ger., 282,781, Dec. 12, 1913. **A. JABS.** Construction of app. for expressing water from peat.

Ger., 282,882, July 24, 1913. **J. MÜLLER and A. BERTHOLD.** In the construction of coke ovens, the passage of gases between the oven proper and the heating channels is prevented by compacted refractory material which is used in the construction of the sepg. walls.

Ger., 282,912, Oct. 24, 1913. **T. VERHOEVEN.** Constructional details of an app. for grinding peat or the like.

Ger., 283,062, July 7, 1914. **H. VOSS and A. PRUST.** Utilization of fine coal by

coking and degasifying. Heretofore fine coal has not been worked successfully in gas manuf. because of the difficulties interposed to the escape of the gases generated, and further because explosions are likely to occur. Also, a high-grade coke cannot be obtained from fine coal alone. To overcome these difficulties, suitably granulated moist brown coal (5 to 15 mm. in size) is added to about 10-15% of the wt. of the fine coal.

Ger., 283,132, Nov. 27, 1913. H. KOPPERS. **Preparing coal for coking.** Dry coal dust is moistened with fat solvent, such as soap soln. (to overcome the surface tension which prevents the absorption of the H_2O by the coal), and to increase the NH_3 yield correspondingly. E. g., the thin layer of coal dust is treated, from both sides, with a finely atomized soap soln. in order to moisten the coal uniformly with a definite small % of liquid. The addition of H_2O to the charge is necessary to prevent the decompn. of the NH_3 normally formed during the distn.

Ger., 283,201, Dec. 29, 1912. PHARMAKON G. M. B. H. In the manuf. of **kindling mass to be saturated with liquid fuel**, wood felt is impregnated with H_3PO_4 and $(NH_4)_2HPO_4$. The fiber is so affected that it permits the complete combustion of the combustible liquid with which it may be satd. The felt, prepared from wood, straw, or the like, after impregnation and shaping, is satd. with a combustible liquid. The impregnating salts prevent too rapid combustion and disintegration of the fiber, and loss of liquid fuel.

Ger., 283,303, Dec. 25, 1913. P. HOSS. **Mfg. a plastic lining for coke oven doors** by mixing 75 parts refractory broken stone from old used coke-oven linings, with 20 parts fire-brick clay, and then adding 5 parts water-glass. Also, up to 10% of graphite as obtained from the oven walls and the vertical tubes are used.

Ger., 283,446, May 21, 1914. H. MÜLLER. **Intermediate pressure regulating tank for use in conjunction with intermittent gas generators.**

22. PETROLEUM, ASPHALT, AND WOOD PRODUCTS.

F. M. ROGERS.

Studies on the pressure distillation of petroleum hydrocarbons. A. P. BJERRE-GAARD. *J. Ind. Eng. Chem.* 7, 573-7(1915).—A detailed report with tables, diagrams, etc., of a series of expts. on the "cracking" of oils. It is shown that the yield is at least roughly proportional to the time the oil is subjected to the influence of heat and pressure. $Mg(OH)_2$ + $Ca(OH)_2$ and ZnO added as "catalyzers" appeared to decrease the yield of gasoline and gas loss, the ZnO more so than the Ca . The lighter or transformation distillates, obtained in the first sepn. of the oils into 2 portions, contained no aromatic hydrocarbons. The high heat and great pressure not only broke down whatever viscous hydrocarbons were originally present in the tars studied, but prevented the formation of others.

F. W. SMITHER.

Asphalt and petroleum in the Philippines. J. F. BOOMER. *Commerce Repts.* No. 170, 358-61(1915).—The division of mines of the Philippine Bureau of Science has examd. the asphalt deposits of Leyte and found large quantities of rock asphalt and some petroleum. The petroleum is a light oil with a high % of gasoline, but it is not yet

detd. whether this can be obtained by drilling wells in the ordinary manner because the rocks are so fine-grained that the petroleum does not flow very readily. E. H.

The present status of the wood turpentine industry. E. H. FRENCH AND JAMES R. WITHROW. *Met. Chem. Eng.* 12, 95-9(1914); *J. Ind. Eng. Chem.* 6, 148-52(1914); *Chem. Eng.* 19, 58-63(1914). E. H.

The hardwood distillation industry in America. E. H. FRENCH AND J. R. WITHROW. *J. Ind. Eng. Chem.* 7, 47-55(1915); *Met. Chem. Eng.* 13, 30-9(1915); *Chem. Trade J.* 56, 119-20, 141-2(1915); cf. preceding abstr.—This paper includes a historical review, a general discussion of the subject and a report on recent exptl. developments and failures. Discussion. H. O. SHUTE. *Ibid* 55-6. I. MILLER.

Apparatus for the recovery of turpentine oil from pine waste-wood, paving blocks and lumber. G. BARNICK. *Leipzig. Chem. App.* 2, 137-8(1915).—A cut shows an app. for extg. with superheated steam; general directions for operating are given.

Brit., 6,345, Mar. 12, 1914. ALLGEMEINE GES. FÜR CHEM. IND. **Separating solid paraffin hydrocarbons** from fractions obtained from coal-tar, shale oil, or petroleum by the addition of liquid SO_2 , which is mixed with hydrocarbons of the aromatic series if the fractions do not already contain such hydrocarbons. The sepd. paraffin may be purified by treating with liquid SO_2 , which may contain aromatic hydrocarbons, at a temp. above the m. p. of the paraffin, such as 40° , in a closed vessel. The method of purification may be applied to solid paraffin obtained by other methods. Cf. C. A. 9, 860.

Brit., 6,536, Mar. 14, 1914. J. M. DESCHAMPS. **Constructional details of charcoal kilns.**

Brit., 6,547, Mar. 14, 1914. H. E. FENCHELLE and F. M. PERKIN. **Cracking hydrocarbons** by heating them in the liquid state under very high pressure and afterwards cooling the liquid still under pressure and allowing it to escape at a lower pressure into a chamber in which the lighter hydrocarbons vaporize spontaneously. The oil is heated to $500-600^\circ$ under a pressure of 50-60 atms. in cracking-tubes and is cooled by passage through a boiler containing H_2O . If the oil is thus cooled to 150° , steam of about 60 lbs. pressure is generated. The oil then passes through throttle valves into a vaporizing chamber fitted with baffle-plates. The gases and vapors generated in the vaporizing chamber pass to a dephlegmator, in which they are sepd. into fractions issuing by suitable pipes. The residual liquid in the vaporizing chamber is run into a still heated by steam-coils, using steam from the boiler. The vapors from the still pass to a dephlegmator, the resulting fractions being collected by suitable pipes. The uncondensable gases are led to a scrubber and are eventually used for heating the cracking-

tubes. The residue from the still is subjected to further cracking. The invention is applicable to liquefied hydrocarbons such as naphthalene or paraffin wax.

Brit., 6,593, Mar. 16, 1914. STANDARD OIL CO. In mfg. gasolene, etc., from fuel oil and other petroleum residues by distg. at $650-850^{\circ}\text{F}$. under a pressure of about 4-5 atms., as in the process of 29,862, 1912 (C. A. 8, 2058), the residue from this operation is distd. to dryness under atm. pressure, and this distillate is submitted to the cracking operation, preferably in admixt. with the fresh charges of fuel oil. The crude gasolene thus obtained is refined with acid and redistd., the residue in the still being again cracked. The pressure in the cracking-still is obtained by means of a valve situated either at the outlet of the condenser or between the still and the condenser.

Brit., 7,112, Mar. 20, 1914. CONTINENTAL-CAOUTCHOUC & GUTTA-PERCHA-COMPAGNIE. Cracking heavy mineral oils by the catalytic action of a hydrocarbon-halogen-aluminium compd., particularly the oily compd. having the formula $\text{Al}_2\text{Cl}_6\text{C}_6\text{H}_6$, which is formed as an intermediate product in the Friedel and Crafts reaction when AlCl_3 , EtCl , and benzene are used as the starting materials. The operation may be effected by boiling the heavy oil with the catalyst under a reflux condenser at ordinary or reduced pressure, or by allowing hot petroleum to flow continuously on to the catalyst heated to 170° . The catalyst may be absorbed in porous materials, such as kieselguhr, in which case the vapor of the oil may be passed over the catalyst. The products are satd. hydrocarbons resembling benzene.

Brit., 7,282, Mar. 23, 1914. W. A. HALL. In cracking oils for the manuf. of motor spirit by a process, such as that described in 24,491, 1913 (C. A. 9, 1245), in which the fraction nonvolatile at $180-200^{\circ}$ is sepd. from the product and the remaining gases and vapors are compressed and condensed together, these gases and vapors are first purified by passage through dehydrated fullers earth, bauxite, kieselguhr, or other mineral substances used in the sepn. of finely divided matter from liquid hydrocarbons. Cf. C. A. 9, 375.

Dan., 18,827, July 11, 1913. N. FALK-HULTGREN and E. H. VIDSTRAND. Mfg. a combustible liquid, similar to benzene, by heating a mixt. of CO or CO_2 and H_2 to at least 2000° . In the reaction are formed, besides H_2O , hydrocarbons, which condense upon cooling to a readily volatile benzene-like liquid. Cf. C. A. 9, 148.

Ger., 282,941, Aug. 6, 1913. J. MÜNNING. Electric detonators for group or time firing.

Ger., 283,330, Oct. 10, 1912. DYNAMIT-AKT.-GES. v. A. NOBEL & Co. In a process of hastening the separation of nitroglycerin from the spent acids, the evolution of SiF₄ is effected towards or at the end of the nitration process, by the addition of fluorides and SiO₂ or salts which are readily decomposed by acid. The evolution of SiF₄ can also be caused by the addition of silicofluorides, alone or in admixt. with SiO₂ or its readily decomposed salts, to the nitrating mixt. The escaping gas bubbles of SiF₄ break up the reaction mass and bring the nitroglycerin to the surface. The gas is formed according to the equation $4\text{NaF} + \text{SiO}_2 + 2\text{H}_2\text{SO}_4 = \text{SiF}_4 + 2\text{Na}_2\text{SO}_4 + 2\text{H}_2\text{O}$. The NaF is mixed preferably with about 8-10% of its wt. of finely slimed light kieselguhr, and about 20 g. of this mixt. are added to 100 kg. glycerol about 5-6 min. before the end of the operation. The period required for the sepn. of the nitroglycerin from the spent acid is in this manner reduced to about 1/3, the normal period. The same

effect is produced by 10–15 g. Na_2SiF_6 to 100 kg. glycerol. If some kieselguhr is added, a still smaller amt. of Na_2SiF_6 is required.

Swed., 36,674, Jan. 10, 1913. J. ANDERSON. A moisture-proof friction surface for matches is made with a binder consisting of a H_2O -sol. silicate (K- or Na-water-glass) to which may be added a glue or gum soln.

25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

The dyestuff situation. ANON. *Commerce Repts.* No. 162, 196(1915).—A brief review of the situation in America brought about by the war. E. H.

Swiss dyestuffs for American use. THOMAS H. NORTON. *Commerce Repts.* No. 166, 278–83(1915).—As a result of the war the Swiss dye works find it difficult to get crude coal-tar products and American manufactures are experiencing a dye famine. The Swiss firms are seeking to obtain coal tar crudes from America, paying for them in finished dyes. E. H.

The dyeing and bleaching of commercial fibers. S. G. BAILEY. *J. Soc. Dyers, Colorists* 31, 46–50(1915).—A discussion of some com. fibers used chiefly in brush, broom and mat making. The action towards dyes, the bleaching properties, and the uses of Bassine or Palmeiro fiber, Mexican fiber, coconut fiber, Kitool, esparto grass and horse hair are described. L. A. OLNEY.

β -Hydroxy-1-naphthoic acid. J. HEILMANN & CO. AND MARTIN BATTEGAY. *Bull. soc. ind. Mulhouse* 1914, 267; *Rev. gén. mat. color.* 18, 281–6(1914).—This acid has had no practical application. Under the influence of various reagents it loses its $-\text{COOH}$ and then furnishes the same derivs. as β -naphthol. There are, however, certain cases where the indirect production of these β -naphthol compds. is a distinct advantage in drying and printing and makes possible results which the use of naphthol would prevent. This acid forms stable alk. salts which are non-volatile with steam, it is equally sol. in alkali carbonates and NH_4OH , and it ppts. Ba and Pb salts and couples just as easily as does β -naphthol. The prepn. of a para red on wool, the production of colored discharges on azo bottoms, the printing of tannin colors and subsequent developing in a diazo bath, and the prepn. of cloth with β -hydroxynaphthoate followed by a surimpression with aniline black are described. Complete printing formulas are given. MILES R. MOFFATT.

U. S., 1,145,072, July 6. A. L. LASKA and A. ZITSCHER. Azo dyes are made by combining a diazo compd. such as diazotized nitroanisidine, nitro or chloro derivs. of aniline, toluidine, naphthylamines or diaminodiphenylurea with an acidyl-2-amino-3-naphthol, e. g., benzoyl-2-amino-3-naphthol, its halogen or nitro substitution derivs., 2-acetylamino-3-naphthol or 3,3'-dihydroxy-2,2'-dinaphthylurea. Red and reddish blue dyes, which yield lakes fast to oil, are formed. Cf. C. A. 8, 1875.

U. S., 1,145,846, July 6. G. R. PESTER. **Forming jasse-melange textile materials.** Undyed cotton and undyed wool yarns are twisted together, a number of the threads thus formed are twisted together and the composite threads are successively dyed in cotton and wool dyes.

U. S., 1,145,858, July 6. J., T. and E. BRANDWOOD. **Apparatus for dyeing.**

U. S., 1,145,934, July 13. A. STEINDORFF and R. WELDE. **Vat dyes of the indanthrene series** are transformed from an amorphous condition to a coarsely cryst. form by heating with about 5–15 times their weight of H_2SO_4 of 1.6–1.67 sp. gr. for several hrs., then dilg. with H_2O , but still leaving the sp. gr. of the acid at 1.5 or more so that

the impurities present will go into soln., filtering off the latter and treating the residue with ice H_2O to dissociate the product containing indanthrene sulfate.

U. S., 1,146,324, July 13. J. H. GILES and D. M. GILES. **Apparatus for dyeing yarn.** Cf. C. A. 8, 3864.

U. S., 1,146,461, July 13. C. TAYLOR. **Bleaching textile fabrics** by satg. with a soln. of Cl and H_2O , pressing the soln. into the pores of the material, treating with NaOH soln. to remove fatty and resinous compds., pressing and steaming under low pressure for 3-4 hrs. while acted on with NaOH soln., again pressing and treating with Cl and H_2O , first with a weak and then with a stronger soln.

U. S., 1,146,987, July 20. H. J. YOUNG. **Hemp fiber** is obtained by crushing the stalks between rollers, immersing for a short time in a 2% soln. of NaOH at a temp. of about 95°, rinsing with acidulated H_2O , pressing out the soln., drying and mechanically sepg. the fibers.

U. S., 1,147,011, July 20. A. E. GARRETT. **Treating woolen goods to prevent shrinking** by first subjecting to a Cl bath, then to a weak soln. of soap and NH_4OH , rinsing, drying and finishing in the usual manner. The goods have less tendency to absorb moisture than is usual after treatment with Cl. Cf. C. A. 9, 1695.

Brit., 1,443, Jan. 19, 1914. CASSELLA & Co. **Mfg. fast dyes** by heating 1-amino-2-methylanthraquinone with S in the presence of an aromatic amine such as *p*-phenylenediamine, benzidine, etc. Cf. C. A. 8, 2488.

Brit., 6,900, Mar. 18, 1914. CASSELLA & Co. A **trisazo dye** is obtained by tetraazotizing *m*-aminophenylazo-2,5,7-aminonaphtholsulfonic acid and coupling with 2 mols. of resorcinol. The product dyes claret-red shades, which may be fixed by after-treatment with $HCHO$. It is suitable for dyeing union goods. Cf. C. A. 9, 383.

Brit., 7,317, Mar. 23, 1914. L. LILIENFELD. In a modification of the process of 25,245, 1911 (C. A. 7, 1616), for **finishing, fillings, loading, or dressing textile fabrics and spun goods with viscose**, the viscose soln. used has a content of caustic alkali which is less than its content of cellulose or hydrocellulose, but which is equiv. to not less than 0.6 of this content.

Brit., 8,577, Apr. 4, 1914. FARBW. v. M. L. & B. **Halogen-containing dyes of the quinoline yellow series**, fast to light, are obtained by the condensation of phthalic acid anhydride, either with a *m*-haloquinaldine or a haloquinaldine or one of its homologs which contain halogen or a Me-group in the *o*-position to the N, and then sulfonating the substituted quinophthalone.

Fr., 468,526, Apr. 25, 1913. R. VIDAL. In mfg. **sulfur dyes**, *p*-aminophenol, *p*-phenylenediamine, *o,p*-diaminophenol, oxyazobenzene, benzeneazocresols, poly-amino- or hydroxyaminodiphenylamine are heated with S in the presence of a phenol, cresol, or mixt. of the 3 isomeric cresols (com.), α - or β -naphthol. New black or blue S dyes are obtained.

Ger., 275,537, May 10, 1913. BADISCHE. **Benzanthrone vat dyes.** See C. A. 8, 3722.

Ger., 277,059, June 12, 1913. Addition to 263,382 (C. A. 8, 257). Brit., 3,682, Feb. 12, 1914. FARBW. v. M. L. & B. In the **manuf. of vat dyes**, the processes specified in Brit., 19,599, 1912 (C. A. 8, 429), and 22,528, 1913 (C. A. 9, 865), for the prepn. of vat dyes, by the introduction of S into the mol. of the condensation product of a haloquinone and arylamine, are extended in that instead of the metal sulfides specified therein other S compds., such, e. g., as thiosulfuric acid or its salts, are employed.

Ger., 281,353, Sept. 19, 1913. Addition to 251,569 (C. A. 7, 422). FARBW. v.

M. L. & B. In the manuf. of concentrated vat preparations, the addition of soaps, such as Turkey red oil, monopol soap, etc., has been found to exert an exceptional solubilizing action on the concd. leuco alkali salts of quinone vat dyes, so that with the aid of these soaps, vat solns. of the quinone vat dyes can be very readily prepared.

Ger., 281,448, Dec. 5, 1913. CHEM. FABRIK GRIESHEIM-ELEKTRO. Mfg. water-insoluble azo dyes by combining diazo-compds., which contain no sulfo- or carboxyl-group, with acidyl-2-amino-3-naphthol.

Ger., 281,837, May 28, 1913. P. HAHN. Constructional modifications in mercerizing machines. Cf. C. A. 8, 2813.

Ger., 281,998, Aug. 30, 1913. T. POSNER. Condensation products of indigo, applicable as dyes or as initial material in the manuf. of dyes, are obtained by protracted heating of indigo and its derivs. (halogenated indigo) with reactive methylene compds., such as Et malonate or Et phenylacetate (in excess or in an indifferent high-boiling solvent or with the aid of Cu powder or other agent facilitating condensation).

Ger., 282,001, Mar. 7, 1913. P. HAHN. Process of mercerizing yarn. Cf. C. A. 9, 1998.

Ger., 282,163, Oct. 24, 1913. Addition to 267,089 (C. A. 8, 828). AKTIEN-GES. FÜR ANILIN-FABRIKATION. In mfg. sulfur dyes, instead of mixing with aromatic amines, nucleus alkyl derivs. of 4-hydroxydiphenylamine are heated together with compds. which upon reduction yield aromatic amines, and with S or polysulfides, to high temps.

Ger., 282,198, Jan. 26, 1913. CASSELLA & Co. Mfg. wool dyes of the pyrazolone series, fast to light and milling, by coupling the tetraazo compds. derived from the sulfonic acids of diaminotriarylmethane, with 2 like or unlike mols. of sulfoarylmethylpyrazolone, its substitution products or arylmethylpyrazolones.

Ger., 282,214, Aug. 3, 1913. ANILINFARBEN- UND EXTRAKT-FABRIKEN VORM. J. R. GEIGY. Mfg. 2,5-diaminodiphenylmonosulfones or 2-amino-5-mono- or -dialkylaminodiphenylsulfones by oxidizing 1 mol. of an aromatic *p*-diamine or its unsymmetrical N-mono- or dialkyl-deriv., in the presence of 1 mol. of an aromatic sulfinic acid. E. g., a soln. of 22 kg. *p*-phenylenediamine in 100 liters HCl of 20° Bé. and 750 liters H₂O is mixed with a soln. of 35.6 kg. Na *p*-toluenesulfinate in 750 liters H₂O, and then 300 kg. of a 20% FeCl₃ soln. is allowed to flow in slowly, with stirring. The resulting 2,5-diamino-4'-methylphenylsulfone (and analogously the 2-amino-5-dimethylamino- or 2-amino-5-diethylamino-4'-methylphenylsulfone) may be readily diazotized and employed for the production of azo dyes.

Ger., 282,223, May 17, 1913. Addition to 246,115 (C. A. 6, 2540). NIEDERLAHNSTEINER MASCHINENFABRIK, G. M. B. H. Dyeing machine.

Ger., 282,251, Oct. 2, 1912. DEUTSCHE GASGLÜHLICHT AKT.-GES. (AUERGES). Weighting silk with the organic or mixed organo-inorganic salts of Sn, Zr, Ti, or other suitable metals, and effecting the hydrolysis in an atm. satd. with steam. E. g., the basic acetates of Zr and Sn, which hydrolyze rapidly, are used, whereby, instead of the undesirable HCl, a weak organic acid results.

Ger., 282,317, Nov. 15, 1913. Addition to 263,655 (C. A. 7, 4080). FARBW. V. M. L. & B. Instead of using the aminodiphenylaminesulfonic acids specified in the principal patent in the manuf. of yellow to brown wool dyes, the *p*-aminocarbazolemonosulfonic acids or their derivs. alkylized or arylized on the carbazole N, are coupled with dinitrochlorobenzene.

Ger., 282,346, Mar. 12, 1914. FARBW. V. L. DURAND, H. & Co. In the manuf. of basic safranin dyes, nitrosomethyl- or nitrosoethyl-*o*-toluidine yields, upon con-

densation with *m*-aminomethyl- or *m*-aminoethyl-*p*-toluidine, dyes of the compn. specified in 80,758.

Ger., 282,374, Feb. 25, 1913. D. MARON. Mfg. amino derivatives of substituted benzimidazoles. Benzimidazoles of the general formula I, in which X = alkyl, halogen or alkyloxy and R = H, alkyl, OH, or NH₂ are treated with concd. H₂SO₄ and nitrates, obtaining thereby 4,6-dinitro derivs. of substituted benzimidazoles of the general formula II. From them, by reduction, are obtained nitroamines and diamines applicable in the manuf. of dyes.

Ger., 282,375, Aug. 14, 1913. D. MARON. Mfg. basic condensation products of the benzimidazole series. The 4,6-dinitro-5-halobenzimidazoles obtained according to 282,374 (*supra*) readily exchange the HI at. for the mono- or dialkyl-amino groups or monoarylamino groups, which can thereby be substituted in the aryl residue with the formation of condensation products of constitution (I) or (II). The new compds. serve in the manuf. of dyes and pharmaceutical prepn.s.

R = H, alkyl, OH or NH₂; R₁ = alkyl, Ph, C₆H₄OH, C₆H₄COOH, C₆H₄NH₂, (C₆H₄S)₂, C₆H₄SO₃H; R₂ = H or, if R₁ = alkyl, then R₂ = alkyl.

Ger., 282,451, July 6, 1913. J. J. FEARON. App. for dyeing textile material.

Ger., 282,452, Dec. 13, 1912. H. ZWINGAUER. Centrifugal app. for cleaning oily textile materials with means for elec. heating the air as it is drawn in, up to 200°.

Ger., 282,501, Sept. 2, 1913, 282,502, Oct. 7, 1913, and 282,503, Oct. 14, 1913. Addition to 263,382 (C. A. 8, 257). FARBW. v. M. L. & B. Mfg. vat dyes. According to 282,501 (addition to 263,382) (*cf. supra*), alkali polysulfides, metal sulfides, metal hydrosulfides, or salts of thiocarboxylic acid, are allowed to act upon the condensation products obtained from haloquinones and arylamines. According to the addition patent 282,502, salts of hydrosulfurous acid can be employed for introducing S into the mol. of the haloquinonearylide, preferably in basic organic diluent. The identical or similar vat dyes are obtained, according to addition 282,503, when thiocarboxylic acid anhydride is allowed to act on haloquinonearylides.

Ger., 282,675, Jan. 17, 1913. F. KOCH. Cleaning wool. At first only the fatty constituents of the crude material are removed by means of chlorinated hydrocarbons; then the impurities not sol. in this solvent, such as wool scale and the like, are removed by rubbing, or other dry treatment. The dust particles removed in this manner are treated with a solvent or series of solvents. A fat solvent is employed which has but little solvent power for salts and soaps. By a suitable defatting and removal of the solvent a condition of the wool can be brought about in which the small lumps cling to the fiber as at first and may be removed by combing, beating, or otherwise, and carried

off with or without a current of air. Also by the addition of kieselguhr the same effect can be produced at any stage of working.

Ger., 282,744, Jan. 1, 1914. Addition to 265,659. W. BORKS. **Waterproofing** and otherwise preserving ship- and net-lines, and the like, by impregnating with a mixt. of Venetian turpentine and wax or waxy substances, instead of with a mixt. of Venetian turpentine, wax, paraffin or the like, and gum soln. E. g., a mixt. of 500 g. Venetian turpentine, 400 g. vegetable wax, 250 g. spermaceti and 300 g. ceresin may be used.

Ger., 282,789, Nov. 27, 1913. VEREINIGTE GLANZSTOFF-FABRIKEN AKT.-GES. Fresh impure viscose may be formed directly into **highly lustrous fibers** by means of H_2SO_4 or other mineral acid in equiv. amt., if on the one hand the acid is kept rather weak (only 10%), and on the other hand the period of passage of the squirted stream of viscose through the acid is made as brief as possible, operating at room temp. In a short time after winding, the threads are thoroughly coagulated and can be washed in the usual manner, dried, and desulfurized.

Ger., 282,947, May 15, 1913. L. SCHREINER. **Dyeing with alizarin** and like dyes, in the presence of mordants or salts which act as mordants, using the vat and subsequently fixing. As dye bath are used (to 100 kg. cotton) 10 kg. alizarin, 2000 liters H_2O , 25 kg. soda, and 8-10 kg. hydrosulfite; the alizarin is reduced in a short time, whereupon the cotton is introduced. It is finally boiled in a 5-10% Turkey-red oil bath. To the bath as also to the mordant can be added Mg-, Ca-, Zn- and other salts. Mg salts form sol. compds. with the reduced alizarin.

Ger., 283,443, July 30, 1914. H. W. KNOLL. In a process of **impregnating cotton** on the spool, the material is treated first on a dressing machine with a dil. soln. of dextrin and gelatin, and dried with hot air. The dried hank is then satd., on a waxing machine, with a soln. of paraffin, Japan wax, turpentine oil and varnish, squeezed by rolling, stretched, and cooled quickly by exposure to the action of a fan.

Ger., 283,717, Jan. 12, 1912. BADISCHE. Mfg. **chrome-containing color lakes** from oxyanthraquinonesulfonic acids, by pptg. the colors of 280,505 (C. A. 9, 1998), at the ordinary or elevated temp., upon substrata, or by means of alkalies or alk. reacting agents. Cf. C. A. 8, 1017.

26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

Proposed standard definitions of terms used in paint specifications. Report of sub-committee of American Society for Testing Materials. *Drugs, Oils and Paints* 31, 54-5 (1915).—Definitions of the following terms: standard, equal to, pure, commercially pure, adulteration, adulterant, bulk, voids, opacity, covering power, hiding power, spreading rate, fineness, crystalline, amorphous, paint, pigment, vehicle, volatile thinner, non-volatile vehicle, tinting strength, color, tint, shade, hue, tone, drying, drier, specific gravity, density, gallon, dry. E. W. BOUGHTON.

Imitation chrome yellow. ANON. *Farben-Ztg.* 20, 1032-4 (1915).—General discussion of the properties necessary in such products. Substitutes are lakes made with a base of $BaSO_4$, $CaCO_3$, etc. A list of suitable dyes is given. Resistance to water, alkali, and light is considered. E. W. BOUGHTON.

Progress in the paint and varnish industries in 1914. W. FAHRION. *Farben-Ztg.* 20, 985-7, 1009-10 (1915).—(1) Linseed oil and substitutes, (2) blown oil, linoxyn and linoleum, (3) boiled oil, driers, (4) colors in oil, (5) stand oil, thickened oil, (6) varnishes and (7) the drying processes are reviewed. E. W. BOUGHTON.

Turpentine and paint legislation in Georgia. ANON. *Oil, Paint and Drug Rep.* 88, No. 3, 11(1915).—Copies of two bills introduced in the Georgia legislature, one providing for the sale of turpentine by net wt. and the other for the formula-labeling of paints.

E. W. BOUGHTON.

The constitution of Chinese wood oil varnishes. E. E. WARE AND C. L. SCHUMANN. *J. Ind. Eng. Chem.* 7, 571-3(1915).—A review of the polymerization of the oil is given. W. and S. believe with Wolff (cf. *C. A.* 7, 2125) that the solidification is due to the formation of a colloidal gel. The effect of rosin in preventing solidification is due to the solvent action of the rosin on the gel. The method of W. and S. for the sepn. of Chinese wood oil from other oils (cf. *C. A.* 8, 3244) was found to be satisfactory for the analysis of heated mixts. of Chinese wood oil and rosin. The Na soaps of both raw and heated Chinese wood oils are insol. in abs. EtOH. The fatty acids from these soaps may be dissolved in 80% EtOH and the oleomargaric acid crystd. by cooling. Expts. showed that rosin has no inhibiting effect on the polymerization of Chinese wood oil.

E. W. BOUGHTON.

Colorless lacquer for metal parts. MAR. *Elektrochem. Z.* 22, 68(1915).—The lacquer is made from 10 parts sandarac, 20 of abs. alc., 2 of camphor and 4 of Venetian turpentine. This should be applied thinly with a soft brush to the slightly warmed articles. A lasting coating very resistant to wear is said to be obtained. W. E. R.

ing a surplus to secure the shade lines desired, passing the sheets through a quickly drying soln., *e. g.*, an alc.-ether soln. of shellac to expand the grains of flour on the sheet, drying, treating with quick drying varnish and turpentine and baking.

U. S., 1,147,066, July 20. J. ADLER. Finishing and coating wooden articles. The surface is treated with "methyl acetone," then with a filler and with several coats of celluloid solns., each successive coat of which contains a quantity of opaque pigment (*e. g.*, lithopone) larger than in the preceding coat. A mixt. of shellac varnish and Fe_2O_3 may be used as filler.

Brit., 7,087, Mar. 20, 1914. BRITISH PATENT SURBRITE CO. and E. G. MEADWAY. A metallic paint is made by dissolving gum mastic in rubber soln. and adding metallic powder, celluloid soln., and celluloid solvent. In the example, the rubber solvent is naphtha and the celluloid solvent amyl acetate.

Brit., 7,126, Mar. 20, 1914. F. C. DONOVAN. A composition for cleaning and polishing painted or varnished surfaces consists of boiled linseed oil, spirits of turpentine, tripoli, and shellac. It may be applied with the cleaning-water, and a final polish obtained by application without rubbing of a mixt. of boiled linseed oil, spirits of turpentine, and shellac.

Ger., 282,959, July 8, 1913. REICHHOLD, FLÜGGER & BOECKING. In mfg. oil varnishes, linoleum masses, or the like, with the aid of copal resins, fats, and especially drying oils, the practice in the past has been to heat the copal resin to a high temp. before the addition of the oil, since otherwise the addition of the oil resulted in the sepn. of solid masses, so-called caking, rendering the product insol. in the usual solvents and, therefore, worthless. This condition is circumvented by adding S, Se, their compds., or substances containing them, to the mass. The S or Se may be added as such, or may be taken up in any solvent which is sol. in the resin-oil mixt. and enters into combination therewith. *E. g.*, the so-called fact has proved satisfactory. When employing such an addition, the copal resin may be mixed with the oils at the ordinary temp. and heated to the necessary temp. without the formation or reversion to insol. substances. *E. g.*, 20 kg. Manila copal are heated to 100–150° with 20 kg. of linseed, and about 200 g. S are added. This mass is again heated, up to 300–320°. A thoroughly uniform mass is obtained which, after cooling, may be dild. with the necessary amt. of turpentine oil.

27. FATS, FATTY OILS AND SOAPS,

E. SCHERUBEL.

The constants of the fatty acids from sulfonated cod oil. L. G. RADCLIFFE AND C. W. PALMER. *J. Soc. Chem. Ind.* 34, 643(1915).—R. and P. used a brown cod oil having sp. gr. 0.931 at 15.5°, sapon. no. 163.3, acid value 17.6, corresponding to 8.9% of free fatty acid calcd. as oleic acid, and iodine value 173.7%. The fatty acids were prepd. by sapon. with strong potash and alc., boiling the soap with water to remove the alc. and pptg. the fatty acids by HCl. The clear oil was washed with water, sepd. and heated until free from moisture. The fatty acids had a solidifying point (titer test) 22.8°, neutralization value 194, mean mol. wt. 289.4, I value 178%, and yield of hexabromides 42%. To 100 g. of oil in a suitable vessel were added, drop by drop, 35 g. concd. H_2SO_4 . The temp. was at no time above 25°. No SO_2 was noticed. After two hrs. stirring the darkened and thickened product was washed with cold satd. soln. of Na_2SO_4 until nearly all of the free H_2SO_4 was removed. The product dissolved in dil. NH_4OH to a clear soln. A clear oil was obtained on heating in the water oven. The fatty acids were prepd. in the same way as from the original oil. They contained no S. They were of much harder consistency than the acids from the unsulfonated

oil. The solidifying point (titer test) was 25.7° , neutralization value 183, mean mol. wt. 308.6, I value 114.4, and yield of hexabromides 11.0%. J. S. ROGERS.

"Kontakt" and "Pfeilring" saponifiers. G. KÖNIG. *Seifensieder Ztg.* 42, 93-4 (1915).—A comparison of these reagents with the following results: The "Kontakt" reagent requires more H_2SO_4 for its activity than the "Pfeilring," a disadvantage when the glycerol water is made neutral with $BaCO_3$. The "Kontakt" reagent is more active at the start. The color of the fatty acids is said to be the same. The ash content of the glycerol from the "Pfeilring" reagent is 0.09%, while that from the "Kontakt" is about 1%. E. SCHERUBEL.

Fat from precipitated muck (BECHHOLD) 14.

U. S., 1,145,480, July 6. C. H. HAUSAMANN. Saturated compounds from unsaturated fatty materials. See Can., 157,396 (C. A. 9, 531).

U. S., 1,147,392, July 20. O. C. HAGEMANN. Refining oils and fats by treatment with caustic alkali followed by addition, after the purifying action of the alkali is completed, of CO_2 , dil. $NaHCO_3$ or H_3BO_3 soln. or other acid which does not materially reverse saponification.

Ger., 282,782, Dec. 12, 1913. BADISCHE. In catalytic hydrogenation and dehydrogenation, the taking on and splitting off of H_2 with the aid of known metallic catalyzers (especially Ni, Co, Fe, Cu) are facilitated and hastened by the addition to the catalytic metal of F, Te, Sb or their compds. Complex compds. are preferred. E. g., 40 parts $NiCO_3$ are satd. with 1 part NH_4 tellurite soln., dried, and reduced. With the aid of such a contact mass, cottonseed oil is hardened at about 100° .

Ger., 282,936, June 21, 1912. LUX-APPARATEBAU- UND VERTRIEBS-GES. M. B. H. Construction of an app. for treating cadavers and other flesh scraps.

Ger., 283,216, Feb. 22, 1914. C. STIEPEL. In a process of deodorizing train oil fatty acids, the vapors of these acids are mixed with SO_2 . The odor does not reappear after such treatment, either in the acids or in the soaps made therefrom. A moderately strong current of SO_2 is passed over the surface of the fatty acid in the still when the temp. of the acid has reached 200° , and continued until the distn. is concluded.

28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

Purity of the juice of individual sugar beets. JOSEF URBAN. Prague. *Z. Zuckerind. Böhmen* 39, 151-63 (1915).—The seed of 2 strains (A and B) of mother beets was sown in the same plot under as nearly as possible identical vegetative conditions; the detns. and observations indicated below were made on 100 beets from each strain. The purity of the juice, as well as the sugar content and other characteristics, of beets of the same strain grown on the same plot of ground was found to vary considerably. The generally recognized relation between sugar content and purity of the juice was observed in the case of various beets of the same strain; beets with higher sugar content showed a greater av. purity of the juice and the reverse relation was likewise true. This relation is not absolutely true, however, inasmuch as instances of correlated high sugar content and low purity of juice were observed in the case of individual beets and also in the comparison of different strains. This "gap" in the correlative nature of sugar content and purity of juice doubtless has a bearing on the fact that mother beets of the same wt. and sugar content sometimes produce descendants which show considerable variations in quality. The generally credited inverse relation between

purity of the juice and wt. of the beet (*i. e.*, the purity of the juice decreases as the wt. of the root increases and *vice versa*) was not observed in the case of beets grown under the same vegetative conditions; roots of varying wt. of both the *A* and *B* strains often showed approx. the same degree of purity of the juice. The av. exptl. data of both strains also contradicted the above supposed relation, since the individuals of strain *B* had both a higher av. root wt. and a higher av. purity of juice than the individuals of strain *A*. Diminished purity of juice was only observed in the case of certain exceptionally large roots grown under conditions of considerable excess of nutrient material. Certain relations between purity of juice and shape, as well as other superficial characteristics, of the root were also observed. A high pointed root top (instead of a lower, rounded shape) was found to be associated with diminished purity of juice; sketches of these 2 typical shapes are given. Diminished purity of the juice is also associated with a greenish coloration of the constricted portion of the root and, in the majority of beets, with a pronounced wrinkled appearance of the surface. H. S. P.

Further experiments on the influence of the rate of saturation on the purity and filterability of beet juice. VL. STANĚK. *Z. Zuckerind. Böhmen* 39, 1-7(1914).—Certain previous observations in factory experience were more carefully tested on a laboratory scale. A cylindrical Cu vessel (with outcurving bottom) mounted on a tripod was used as a satn. kettle. This vessel was equipped with a stirrer and CO_2 , after passing through a rotameter, was introduced through a tube with perforated tip which passed to the bottom of the vessel. A 1 chamber filter press was employed; the filtering material (fine linen cloth on 3 layers of filter paper) was placed on a metal sieve which rested in turn on the lower plate (the latter was fluted and the channels connected with the outlet) of the filter press. Fifteen hundred g. diffusion juice (passed through a fine sieve) were placed in the satn. kettle and heated to 85° with const. stirring; 2.1% CaO (calcd. on the basis of the amt. of juice) was then added in the form of milk of lime of known concn. and the mixt. was stirred 10 min. at 85° . Satn. with CO_2 was then commenced and continued to a content of approx. 0.1% CaO , the degree of alkalinity being approx. measured by means of Karlik phenolph. reagent paper; 600 l. and 100 l. CO_2 per hr. were employed for rapid and slow satn., resp. Foaming was prevented by addition of xylene (which was removed by heating) in amts. of 1-2 g. at a time. After the 1st satn. was complete the filter press was attached to the bottom of the kettle by means of a screw nozzle provided with a cock; the satn. kettle was then hermetically closed by means of a top plate equipped with a manometer and inlet for compressed air. The contents of the kettle were brought to a definite vol. of 1500 cc. with H_2O and a const. pressure of 1.5 atn. was maintained during filtration. The ppt. remaining in the filter press was washed with hot H_2O until the filtrate amounted to 150 cc. (which was added to the juice). The juice, satd. and filtered as above, was then heated to 90° and subjected to a 2nd satn. so that the CaO content was reduced to 0.01%, after which it was boiled 10 min. on a sand bath, filtered, cooled and analyzed (detn. of ash, N, sugar, color, CaO , content of dry substance). The CaO content of the juice after the 1st and 2nd satn. was 0.08-0.13 and 0.005-0.011%, resp. The period required for satn. was found to decrease with increasing purity of the diffusion juice as well as with increasing rate of inflow of CO_2 . The rate of filtration of rapidly satd. juice was in all cases greater than that of slowly satd. juice. The rate of filtration increased as a rule with increase in the coeff. of purity in the case of both the rapidly and slowly satd. juice; no definite relation could be ascertained so it is probable that the interdependence is of a complicated nature. The coeff. of purity of rapidly satd. juice was greater than that of slowly satd. juice; the content of N, ash and pigment was less in the former than in the latter. S. is now constructing an app. by which to measure the velocity with which CO_2 is absorbed by milk

of lime under varying conditions (influence of varying amts. of sugar and non-sugars, as well as the effect of different temps., manner of slaking the CaO, etc., on the course of satn.). The C content of the organic non-sugar substances of CaO ppt. (from diffusion juice) which had been dried at 50° and kept for 1/2 yr. was found to have increased during this time; this indicates that some sugar had been transformed by the action of CaO and air into other organic compds. and recalls a similar observation of Urban in the case of Sr saccharate. The action of microorganisms is not excluded, but is, however, not probable.

H. S. PAINE.

The determination of reducing sugars by the Bertrand method and the influence of sucrose upon the results. H. PELLET. *Intern. Sugar J.* 17, 273-4(1915).—P. criticizes Bertrand's method which does not point out errors due to the presence of sucrose, and the duration and intensity of boiling. P. avoids the action of sucrose by heating the mixt. of cupro-potassic liquor and sugar soln. only to 60-62° during 10 min., commencing at the moment when the liquid reaches this temp. Parker's method is recommended for the volumetric detn. of the Cu₂O when the amts. are too small to be weighed. If 0.5 g. of salicylic acid is added to a standard soln. of invert sugar at the time of inversion, the soln. will keep indefinitely.

A. GROSS.

By-products of sugar manufacture. C. W. HINES. *Sugar* 17, No. 6, 44-6(1915).—The various sugar-house by-products of the Philippine Islands are described and a plea is made for their utilization.

A. GROSS.

The by-products of the cane sugar factory. W. E. CROSS. *Intern. Sugar J.* 17, 267-71(1915).—The article deals mainly with the fertilizer value of filter press cake. Analyses of the press cake from seven factories in Tucuman on air-dried samples showed the comp. to be P₂O₅ 3.04-7.81, N 1.87-2.75, NH₃ 2.27-3.33, the variation being due to the method of clarification used. There was some loss of organic substances due to the weathering process of drying the cakes but the loss of N was not of important dimensions. The phosphoric acid is present to a large extent in citrate-sol. form, but mostly so when H₂PO₄ is used in clarification. The lime is present in good proportion and the organic matter (about 50-70%) is a humus-producing material of considerable value. C. suggests that this is a product of value and should be returned to the soil if the fertility of the land is to be maintained.

A. GROSS.

Dehydrated cossets. F. G. WIECHMANN. *Sugar* 17, No. 6, 29-31(1915).—To prolong the sugar beet campaign, W. suggests the working of dehydrated cossets during the usual dull period. The cossets are prepd. during the working season by a special method of hydration (details of procedure not given) and stored for future use. After 100 days storage the sucrose differed by only ±0.2%. The saving in transportation and storage is considerable as the dehydrated cossets weighed only 25% of the original. A practical test was made with the dehydrated cossets and the results obtained were in all respects equal and in some respects superior to the results obtained from fresh beets worked in the same factory.

A. GROSS.

U. S., 1,145,484, July 6. F. W. HUBER and R. W. POINDEXTER, JR. **Obtaining ammonia, hydrocyanic acid and other by-products from beet-molasses waste water.** "Steffen's water" is concd. and subjected to destructive distn. The gases produced are heated to above a red heat, producing HCN, first cooled to effect sepn. of tar, then washed with acid to recover NH₃ and further cooled to condense H₂O, which carries with it at least part of the HCN.

U. S., 1,146,456, July 13. W. SEARBY. **Sugar cane** is crushed to break and flatten it, then shredded by beating and re-pressed to recover the saccharin juice.

Brit., 2,813, Feb. 3, 1914. AKT.-GES. FÜR ANILIN-FABRIKATION. **Betaine and**

its salts are prepd. by evapg. *in vacuo* the molasses, etc., obtained from beet-sugar manuf., and then adding HCl soln. so that the temp. does not rise high enough for the formation of humus substances. On cooling, betaine-HCl crystallizes out and may be purified and converted into betaine or other salts thereof in the known manner.

Brit., 2,923, Feb. 4, 1914. AKT.-GES. FÜR ANILIN-FABRIKATION. Betaine salts are obtained from molasses and other beet sugar residues by rendering the material feebly acid in reaction with HCl or other acid, and then evapg. the mixt. *in vacuo* at a temp. not exceeding 60°. The betaine salt crystallizes out on cooling, and its sepn. may be hastened by strongly acidifying the soln. with HCl.

Ger., 281,830, Oct. 19, 1912. M. S. HANSEN. In mfg. potato starch by bacterial fermentation with exclusion of air, the coarsely comminuted potatoes are subjected, for several days, in a closed vessel under H₂O, maintained at a temp. of 25-40°, to spontaneous fermentation.

Ger., 281,925, Dec. 2, 1913. M. LINDNER. In a process of purifying sugar juices obtained according to 268,530 (C. A. 8, 1885), the thick sap obtained from the sugar beet cuttings treated with Al(OH)₃ in neutral or alk. soln., is treated with colloidal Al(OH)₃ at 70-80°, for the purpose of removing the non-saccharin residues contained therein. This is not preceded by a treatment with lime. The Al(OH)₃ residue is sepd. by means of dil. lime water; the mass is boiled and filtered.

Ger., 282,445, Jan. 7, 1913. L. VENDITI. App. for treating the residues of sugar manufacture.

Ger., 282,810, Nov. 9, 1913. O. GIESS. Mfg. a high-% clear sugar sirup, non-cryst., with over 50% sugar content, by keeping the amt. of the saccharose, with reference to the invert sugar, in the proportion of 5:2. Such a product is of value in those processes in which the sugar must not be fermented too readily.

29. LEATHER AND GLUE.

LLOYD BALDERSTON.

Vegetable tanning materials in 1914. J. JEDLIČKA. *Gerber* 41, June 1 and July 1 (1915); *J. Am. Leather Chem. Assoc.* 10, 441 (1915).—A general discussion and review.

E. J. C.

Wattle bark supplies of British colonies. ANON. *J. Roy. Soc. Arts* 63, 753 (1915).—Production statistics.

E. J. C.

Neradol D. A. ROGERS, *et al.* Tanners Inst., Brooklyn. *Repts. of 3rd yr.* 25-30, 38-42; *J. Soc. Chem. Ind.* 34, 368 (1915).—Preliminary treatment with Neradol D renders vegetable tannage more rapid at first but does not influence the final yield of leather. Calf skin, pickled as for chrome tannage, gave a similar yield with a combination of Neradol D and quebracho as with quebracho alone; Neradol D alone did not give so good a yield of leather.

E. H.

Peptization phenomena in tanning solutions. W. MOELLER. Hamburg. *Kolloid-Z.* 16, 69-76 (1915); *Collegium* 1915, 49-59.—Tanning solns. contain 2 essential components, a peptizing material which is sol., and an insol. material which in contact with the former is peptized to a colloidal soln. The tanning effect is due to the adsorption of the peptizing material by the hide, which causes coagulation of the peptized material in the leather. Tannin is the peptizing material in most vegetable tanning materials, while the insol. materials are related either to pyrogallol or to pyrocatechol. These are usually found in different parts of the same plant, and the tannin present may be in excess, or insufficient to peptize all of the insol. material available. Tanning

with inorg. materials is due to the presence of a sol. or an insol. hydroxide which is peptized by the normal or acid salt.

H. I. MATTILL.

Note on the analysis of tanning materials. THOMAS CALLAN. *J. Soc. Chem. Ind.* 34, 647(1915).—Analyses were made of guara using (1) the present official method of the Assoc. of Leather Trades Chemists with American hide powder of standard quality, (2) Bennett's method (*C. A.* 9, 978) using American standard hide powder and (3) Bennett's method using finely ground hide powder obtained from the Deutsche Versuchsanstalt für Lederindustrie, Freiberg. The non-tannins obtained, using the same soln., were 23.1%, 28.1%, and 25.4%, resp. The gelatin test on the detannized solns. showed no turbidity nor opalescence, thus indicating apparently complete detannization. (2) showed the least absorption of non-tannins. By Stiasny's test (to 3 cc. of the soln. to be tested add 1 cc. of a satd. salt soln., then 2 drops of 1% HPO_3 soln., and finally 2 drops of 5% gelatin, 5% salt soln.) on the non-tannin filtrates, (1) and (3) showed no tannin, and (2) a distinct trace. After redissolving the dried non-tannin residue, (1) gave no reaction, (2) a heavy ppt., and (3) distinct opalescence. Expts. were made to det. the approx. degree of accuracy of the present official tannin test. It was found that with some tannin materials 6.5 mg. in 50 cc. could not be detected by the official method, although Stiasny's readily showed 3 mg. in 50 cc. A stringent test would be to concentrate 6 cc. of the presumably detannized soln. (12 cc. if Bennett's method is used) to 3 cc. and apply Stiasny's test. It would seem by a number of analyses that the Bennett alteration designed to reduce the absorption of non-tannins had been carried too far. Stiasny's test will not show 150 mg. of gallic acid in 50 cc.

J. S. ROGERS.

Notes on the analysis of guara and guara extract. THOMAS CALLAN. *J. Soc. Chem. Ind.* 34, 645(1915).—Nearly all the reactions of guara tannin agree closely with pyrogallol tannin. A dil. aq. infusion gives a violet-blue coloration with iron alum, no ppt. with Br water, no phloroglucinol reaction with a deal shaving, a yellow ppt. turning green with lime water, a slight ppt. with HCHO and HCl , a yellow coloration with Na_2SO_3 , and intense red or brownish red coloration with an ammoniacal soln. of $\text{K}_3\text{Fe}(\text{CN})_6$ in a very dil. soln., a pink to purple coloration with Bennett's I test, and a deep orange-brown color with nitrous acid. However, with concd. H_2SO_4 a crimson-pink coloration changing to pink is obtained, a reaction given by most catechol tannins. A table of analyses shows that the past two years' supply of guara has been of a remarkably constant quality. One set of results is 44.8% tans.; 23.1% non-tans.; 21.7% insol. and 10.4% H_2O . Skins tanned entirely with guara give a soft well-filled leather resembling gambier tannage. This may be due to the nature of the non-tannins. Guara is not liable to give excessive fermentation. It is not readily leached on account of its fine state of subdivision, although the tanning matters are readily sol. For developing acidity in tan liquors guara is excellent, and used with untreated quebracho it gives a good color. Used in the paddle with quebracho, guara does not draw the grain, but gives a soft mellow tannage. Guara extract is inferior in all respects to the natural product and is no longer imported.

U. S., 1,147,178, July 20. M. B. LARSON. Composition for tanning hides and skins, formed by separately dissolving gambier 5 and NaCl 1 part in hot H_2O , combining the solns. and adding 1 part of MgSO_4 .

U. S., 1,147,245, July 20. H. H. HURT. Preparing a tanning composition from

waste sulfite liquor. Highly concd. neutral or nearly neutral waste sulfite liquor is treated with H_2SO_4 to ppt. part of the Ca and liberate lignosulfonic acids, then NaHSO_4 is added to ppt. the remainder of the Ca and after sepn. of the ppt. there remains a concd. soln. of about $28-31^\circ \text{Bé}$.

Ger., 281,822, Mar. 24, 1914. **BAYERISCHE MASCHINENFABRIK REGENSBURG F. J. SCHLAGETER.** Mounting for a **tanning and fulling trough**, revoluble around its middle axis. The trough, tightly closed on all sides, is allowed to float freely within a liquid container.

Ger., 281,868, Oct. 30, 1913. **C. MÜLLER.** Machine for **defatting animal scrap, skins**, and the like, whereby the material is conducted, by means of endless bands, between electrodes in alk. bath.

Swed., 36,696, Feb. 10, 1912. **K. BENDIXEN.** **Tanning fish skins** by softening them, allowing them to lie for 3 days in a soln. of As_2O_3 or Na_2S or both, rinsing them, and leaving them for 3 days in a soln. of slaked lime and H_2O . During this period the skins are taken out frequently and spread out. They are then treated for 5 min. with a weak HCl soln. and finally with H_2O , poultry dung and salt liquor, or in a soln. of sumac ext.

30. RUBBER AND ALLIED SUBSTANCES.

R. T. STOKES.

Spots on rubber. ANON. *India Rubber World* 52, 569(1915).—Spotting and discoloration are generally due to common saprophytic fungi which contain proteolytic enzymes, infection taking place while latex is being collected. Diln. of the latex increases the danger of infection. Infection is best prevented by treating the latex with formalin, by the quick drying of rubber, and by the addition of NaHSO_3 .

H. B. SLUSSER.

Rubber latex prepared with uranium borate. ANON. *India Rubber World* 52, 569(1915).—It is stated that 8 oz. of U borate to every 100 lbs. of latex, when thoroughly mixed with the latex before coagulating, influences considerably the appearance of the rubber, prevents oxidation, and increases tensile strength.

H. B. SLUSSER.

The estimation of sulfide and sulfate sulfur, and the action of solvents on vulcanized rubber. HENRY P. STEVENS. *Analyst* 40, 275-81(1915); cf. C. A. 8, 2267. —*Detn. of sulfide S:* The app. consists of a Kipp CO_2 generator and a Voigt flask. This is a 250 cc. flask with an outlet tube connected to the ground-in stopper, and an inlet tube fused in the side and reaching nearly to the bottom. 10-20 cc. pure concd. HCl are poured into the flask and covered with a layer of ether (20-30 cc.). The air is then swept out of the app. with CO_2 and the stopper removed for a few seconds to admit the entry of the rubber (0.1-1.0 g.). If the rubber tends to sink in the acid soln., it is advisable to swell it with ether alone before placing in the flask, or to wrap it in filter paper to keep it afloat. Two 100 cc. absorption bottles containing Pb acetate soln. are connected to the app. and a little more CO_2 passed through to drive out traces of air. The whole is allowed to stand with occasional shaking for 15-30 min. for soft rubbers, or longer for hard or fully cured specimens. The rubber swells and is gradually decompd. by the acid with the evolution of H_2S . The ether and H_2S are now driven over by gentle boiling, and the decompn. completed by boiling a few min. Traces of H_2S are washed out with CO_2 , and the whole is allowed to cool. The absorbing liquids are acidified with AcOH to decompose any carbonate formed, and the PbS filtered off cold and washed on the filter until free from sol. Pb salts. It is transferred wet to a stoppered flask, and allowed to stand with occasional shaking in contact with a known vol. of standard I soln. The excess of I is then titrated with $\text{Na}_2\text{S}_2\text{O}_4$. *Estn. of sulfate S:*

The soln. remaining in the Voigt flask should contain the PbSO_4 resulting from the reaction $4\text{PbO} + 2\text{S}_2 = 3\text{PbS} + \text{PbSO}_4$. Repeated extns. of the residual rubber with HCl were made, but the theoretical amt. of PbSO_4 was not obtained. This indicates that, although the above equation expresses the reaction of PbO and S in an inert medium the reaction is modified in the presence of caoutchouc. Repeated extns. with HCl and ether showed that when swollen rubber is extd. a small part of the vulcanized rubber passes into the soln. with the S. The whole of the S in a vulcanized compd. containing PbS and ZnS may be accounted for as follows: (1) Free S by oxidation of the acetone ext.; (2) sulfide S by decompn. with ether and HCl, and estn. of the H_2S ; (3) sulfate S in the HCl soln.; (4) S combined with rubber by oxidation of the residue. Although it is generally held that fully vulcanized rubber is not sol. in common solvents, the expts. made show that in the presence of HCl vulcanized rubber is dissolved even in the cold. Mixtures of benzene and HCl and of chlorohydrocarbons and HCl have a solvent action similar to that of mixts. of ether and HCl.

P. B. DUNBAR.

U. S., 1,145,351, July 6. S. C. DAVIDSON. Obtaining rubber from latex by treatment with an alkali metal polysulfide or thiosulfate and then with acid of 1-2% strength which forms free S in the rubber during the coagulation. The S thus deposited acts more uniformly during vulcanization because of its fineness and even distribution. Disinfecting agents such as CH_3O or an alk. soln. of creosote or PhOH may be added during the process.

U. S., 1,145,352, July 6. S. C. DAVIDSON. Coagulating rubber latex after successively adding a dil. alk. soln. of creosote and CH_3O and an acid, *e. g.*, HOAc, HCl or H_2SO_4 .

U. S., 1,146,253, July 13. A. HEINEMANN. Caoutchouc from isoprene is made by passing O_2 or O_3 through the isoprene and then heating at 105° to effect polymerization. On heating for 8 days a 50% yield is obtained. The O_2 may be generated in the isoprene if desired by mixing BaO_2 and H_2SO_4 with it or from H_2O_2 or by electrolysis of H_2O .

U. S., 1,146,699, July 13. T. GARE. Method of mechanically uniting softer vulcanized rubber with powdered ebonite and forming the product into continuous lengths.

U. S., 1,146,851, July 20. S. C. DAVIDSON. Coagulating India rubber latex. An aq. soln. of caustic alkali, cresol, CH_3O and alkali metal polysulfide is added to the latex to serve as preservative and vulcanizing agent and then the latex is coagulated by the addition of HCl, H_2SO_4 , HOAc or $\text{CCl}_3\text{CO}_2\text{H}$ in 0.25-0.5% aq. soln.

Brit., 6,215, Mar. 11, 1914. R. S. AGAR. In coagulating rubber latex, a horizontal drum, grooved, corrugated, perforated, or plain, is rotated in a trough containing latex, the drum and trough being arranged within a smoke chamber to which smoke is fed by a pipe the end of which opens into the trough at a point near the surface of the latex.

Brit., 6,763, Mar. 17, 1914. APSLEY RUBBER CO. Vulcanizing India rubber boots and other articles of irregular shape by placing them upon a last enclosed, with the boot, etc., thereon, in an impervious bag-like flexible envelope, which excludes all air or steam, and by then submitting the article in a vulcanizing-chamber to the action of heat and pressure derived from a fluid. Any excess of air in the bag may be removed before closing it.

Brit., 6,897, Mar. 18, 1914. F. E. MATTHEWS and E. H. STRANGE. Purifying unsaturated hydrocarbons containing the conjugated double bond by first treating them with SO_2 in the presence of HCl or other halogen acid, I, or acid chlorides such as

acetyl chloride, sulfonyl chloride, or thionyl chloride, whereby is obtained a mixt. of sulfo-oxides consisting chiefly of a cryst. substance sol. in H_2O , etc., with a small proportion of an insol. amorphous substance, then sepg. the cryst. sulfo-oxide from the mixt., and decomposing it by heat into the original hydrocarbon and SO_2 . *E. g.*, isoprene is treated with SO_2 and alc. HCl .

Brit., 7,370, Mar. 24, 1914. S. J. PEACHEY. The vulcanization of natural or artificial caoutchouc or caoutchouc-like substances is accelerated by means of a compd. resulting from the interaction of an aromatic amine with an aliphatic or aromatic aldehyde or of an aromatic aldehyde, such as $HCHO$ -aniline, benzylidene-aniline, or hydrobenzamide, with NH_3 . As an example, 100 parts of rubber are mixed with 10 parts of S and 1 of $HCHO$ -aniline, and heated to 140° for about 40 min.

Fr., 468,755, Feb. 20, 1914. M. FRÄNKEL and RUNGE. In mfg. fabric impregnated with rubber, regenerated rubber, alone or in admixt. with crude rubber, may be employed if, instead of the final product of the process of regeneration, are used the emulsions composed of rubber, solvent, and H_2O , and obtained as an intermediate product. Materials impregnated with these emulsions need no further vulcanization.

CHEMICAL ABSTRACTS

Vol. 9.

SEPTEMBER 20, 1915.

No. 18.

I. APPARATUS.

L. C. JONES.

Modified buret calibrating pipet and certain points in the use of such instruments. C. W. FOULK. *J. Ind. Eng. Chem.* 7, 689-93(1915).—The two-way cock is used as the zero mark instead of a mark on the pipet. A discussion of the principles underlying the calibration and use of such pipets is given, as well as extensive directions for manipulation.

ISADOR MILLER.

A simple buret reader. L. S. PRATT. *J. Am. Chem. Soc.* 37, 1730-1(1915).—P. has investigated the different forms of buret readers available and has found that "the various devices possess rather marked disadvantages." The simple reader described (with drawings) has proved to be entirely satisfactory. It consists of a disk of ordinary mirror glass, about 15 mm. in diam., in the center of which is a rectangular section, about 4×10 mm., from which the silvering has been scraped. A fine diamond line extends across the face, perpendicular to the long axis of the triangle. The procedure in using this reader is outlined.

E. J. C.

Adjustable burner support for condensation apparatus. H. E. BISHOP. *J. Ind. Eng. Chem.* 7, 693(1915).—Modification of app. of Barnard and B. (*J. Am. Chem. Soc.* 28, 999(1906)) so as to make it applicable for flasks of any size. All parts can be adjusted separately. The modification was effected by changing the position of the gas supply from under the flask support to the top of the supports for the condensing tube and making the position of the burner adjustable.

ISADOR MILLER.

A simple viscosimeter for determining the inner friction of volatile liquids and of liquid mixtures of volatile substances. O. FAUST. *Z. Elektrochem.* 21, 324(1915); cf. *C. A.* 6, 3043.—To obviate the loss due to evapn., especially at temps. near the b. p., in the detn. of viscosity of volatile liquids by the Ostwald viscosimeter, the app. shown in the cut was devised. This is a modification of a form previously reported (*Z. physik. Chem.* 79, 98(1912); cf. *C. A.* 6, 3043). Liquid is introduced through the side arm *d* which is closed by means of a cork stopper. To bring the liquid above *a*, close and apply suction at *g*, the cock *b* being open. Now open *c* to equalize the pressure and close *b* to prevent any evapn. After filling, *d* is also closed. A rubber tube provided with a pinchcock can be substituted for the cock *b*. To force liquids near the b. p. up into the capillary, close *c* and apply blast at *e*.

F. W. SMITHER.

Note on a new analytical suction filter. JOKICHI TAKAMINE, JR. *J. Am. Chem. Soc.* 37, 1519-20(1915).—This app. has been designed to facilitate the use of suction in making filtrations in quant. detns., in which it is desirable to catch the filtrate in the vessel in which it is to be further treated. The main body of the app. consists of a cylindrical glass jar, near the upper rim of which is a suction outlet with a ground-glass stopcock. The top has a pouring lip in the side opposite the suction outlet and the entire upper surface is ground. Half way up from the bottom on the inside surface are,

at equal distances apart, 3 glass protrusions for supporting a perforated shelf. The cover has a ground-glass rim and has an extra large stopper opening in the center for inserting the filter. The use of the shelf depends on the size of the vessel used for collecting the filtrate. The jar itself may be used as container for further treatment of the filtrate.

E. J. C.

A simple laboratory apparatus for the determination of carbon dioxide by loss. STUART P. MILLER. *J. Am. Chem. Soc.* 37, 1730(1915).—The app. is of the Schrötter type, but is much simpler and less expensive. Tests using C. P. BaCO_3 have shown that an accuracy of 0.1% is attainable with this app.

E. J. C.

New and improved form of Kjeldahl distillation apparatus. A. D. HOLMES. *J. Ind. Eng. Chem.* 7, 693-4(1915).—Modification of app. described in *C. A.* 9, 1.

ISADOR MILLER.

A new assay balance. ANON. *Mel. Chem. Eng.* 13, 512(1915).—The wts. are circular, perforated, metal disks, and are normally supported on upright posts that pass through circular openings in a horizontal frame which is a part of the wt.-pan hanger. On depressing keys outside the case, these posts are lowered so that the wts. rest on the horizontal frame.

W. L. BADGER.

An alternating current thermoregulator. HAROLD S. DAVIS. *J. Am. Chem. Soc.* 37, 1520-1(1915).—D. has constructed an arrangement which adapts the electromagnetic thermostat regulator to the use of a. c. from city mains. The app. has proved satisfactory.

E. J. C.

Some new forms of apparatus. I. A substitute for the twin-bulb trap in toluene-mercury thermoregulators. P. B. DAVIS. *J. Am. Chem. Soc.* 37, 1198-9(1915).—The toluene-Hg regulator described and pictured has been designed to overcome the disadvantages (enumerated) of the twin-bulb device. It has a range of about 50°. II. A new form of pycnometer for liquids. P. B. DAVIS AND L. S. PRATT. *Ibid* 1199-1200.—The authors tried a modified form of the Sprengel pycnometer, as described by Jones and Bingham (*Am. Chem. J.* 34, 48 (1905)) and Jones and Veazey (*Z. physik. Chem.* 61, 641(1908); cf. *C. A.* 2, 1653) and found it to have certain disadvantages. To remove these the form described (with a drawing) was designed. The new instrument is convenient to use and gives accurate results.

E. J. C.

A simple stone-frame chemical hood. E. R. WEAVER. *J. Am. Chem. Soc.* 37, 1726-9(1915).—A detailed description, with drawings, of a novel type of hood installed at the Bur. of Standards. A number of advantages are claimed. There are no doors or other movable parts. A specially designed front is shown for use in labs. where a hood with doors is required. Two-compartment hoods of the type described (without doors) have been in use for nearly 2 yrs. and have given perfect satisfaction. Fumes of all densities are removed with equal facility. Anemometer tests were made to det. the vol. of air required to give good ventilation. Experience has shown that no doors are needed for hoods of this type to insure adequate ventilation, if efficient fan capacity is provided.

E. J. C.

A laboratory stool. HORACE G. DEMING. *J. Am. Chem. Soc.* 37, 1518-9(1915).—The stool described and pictured is an ordinary camp stool of strong construction made to serve as a device for locking the drawers and doors of the student's compartment.

E. J. C.

Device for taking continuous samples of waste water. A. D. GRASWINCKEL. *Arch. Suikerind.* 22, 703-4(1915).—A small pipe is tapped into the condenser fall-pipe near the floor level. The sample bottle has a loose cork with a T-tube, the straight piece of the T being horizontal. The branch of the T inside the cork has attached to it a glass tip with an orifice to correspond to the size of the sample desired. The water

diverted through the small side pipe is passed through the T and on into the hot-well. Thus an av. sample may be taken over any length of time. The same device may obviously be used for any liquid flowing in a pipe.

W. L. BADGER.

Mechanical ore sampler. J. H. TAYLOR. *Eng. Mining J.* 100, 229(1915).—The sprocket wheel *A* (see cut), gear *A* and disk *A* are keyed to the shaft and driven by a sprocket wheel on the shaft of the driving pulley of the belt conveyor. The gear *A* drives an idle gear, which in turn drives gear *C*. Gear *C* and disk *C* are of one piece. As gear *A* has 31 teeth and gear *C* 30 teeth, disk *A* will revolve 30 times, while disk *C* revolves 31 times. At the beginning of one revolution of each 30, the recesses in disks *A* and *C* will coincide and a roller will engage disk *A* for half a revolution, when it will be released. Hence a sample will be taken once in 30 revolutions. The length of the cranks are such that a crank passes through the middle 60° of the 180° while the sample is being taken, so that the increment of the swing of the sample chute is nearly constant, while the stream of flow is actually being cut. With disks $4\frac{1}{2}$ in. in diam. and a crank 12 in. long, this device will successfully sample ore crushed to 4 in. from the end of a belt conveyor 2 ft. wide. The finer the ore the more accurate the daily sample. The device will cut about 0.5% of the ore passing over the end of the belt conveyor, without selection. The sample so taken will not be so accurate for a given day as if taken by cutting 20% each time, but at the end of a week the errors will be largely compensated.

F. W. SMITHER.

New sampling plant at Hamburg, Germany. ANON. *Eng. Mining J.* 100, 140-1 (1915).—The plant was erected primarily for the sampling of FeS_2 cargoes. The ore is reduced to 2 in. lumps and is then passed through a Brunton sampler, where $\frac{1}{4}$ of the stream is rejected. The remaining $\frac{1}{4}$ goes through the gyratory crusher and is reduced to $\frac{3}{8}$ in. lumps; thence to the top of a special automatic sampling machine, consisting of a large steel frame about 14 ft. high, in which are arranged 3 pairs of rolls. The largest, at the top, are 20 in. in diam. and the other 2 pairs are 16 in. and 12 in., resp. Above the top pair of rolls and intermediate between the different sets there are 3 flat reciprocating vanes, flaps or dividers, connected together and arranged to flap from side to side, so that during a portion of the time the ore striking them is diverted in one direction and during the remainder of the time in another. On entering the top of the machine the first flap rejects $\frac{1}{4}$ of the ore. All three of these flaps are driven by cams connecting rods in such a way that during $\frac{1}{4}$ of the time they are deflecting the stream of ore into the rolls and during the remaining time they are diverting it out of the left-hand side of the machine. The first pair of rolls crushes the ore to about $\frac{3}{16}$ in. lumps; this passes over the second flap, the sample going through the second pair of rolls. After another reduction it is finally crushed to the desired degree of fineness by the last pair of rolls; then it goes through a shaking screen and thence to the bottle filler. If there are any particles of ore which have not been sufficiently reduced in size by the last pair of rolls, they slide off the side of the shaking screen upon a little rubber belt elevator, which carries them up and again passes them through the final pair of rolls. In this way the whole of the final sample is crushed to any requisite fineness for the sample bottles. The bottle filler consists of a revolving table on which the bottles are placed and over them an annular hopper divided into compartments so arranged that a certain portion of the final sample is diverted and fed into the bottle in such a way that a definite quantity goes into the bottles and each bottle gets its correct proportion. Another feature of the machine is the provision of automatic adjustable feeders between the sets of rolls for keeping the stream of ore practically uniform. When each set of bottles is filled it is immediately removed, stoppered and sealed

by the representatives of both parties. Careful tests show the results obtained to be very accurate, with only a minute difference in the analyses from different bottles filled at the same time and representing the same parcel of ore. A 5000 ton cargo can be sampled in 3 days by 3 men.

F. W. SMITHER.

The distillation of water. G. W. McKEE. *Am. Gas Light J.* 102, 404-7(1915).—A general discussion including illustrated descriptions of 17 different types of direct-fired stills of American manuf.

E. J. C.

Centrifugal pump for thick liquors. ANON. *Met. Chem. Eng.* 13, 512(1915).—A pump with wide passages and an overhung, open impeller. Advantages claimed are efficiency, slight overload on the motor at heads below the rating, accessibility, and no chance of clogging.

W. L. BADGER.

Pneumatic conveyors in modern factories. J. E. BRAUER-TUCHORZE. Hanover. *Chem. App.* 2, 164-6(1915).—Five cuts and general remarks on air conveyors and separators.

2. GENERAL AND PHYSICAL CHEMISTRY.

WILLIAM D. HARKINS.

Assistants: E. B. MILLARD and A. B. CARTER.

Joseph A. Holmes. V. H. MANNING. *J. Ind. Eng. Chem.* 7, 712-5(1915).—An obituary. ISADOR MILLER.

Constitution of matter and the evolution of the elements. E. RUTHERFORD. *Pop. Sci. Monthly* 87, 105-42(1915).—An exceedingly interesting popular lecture in which the following topics are treated: Crystal structure (Bragg's work), spectra of gases, electron theory, unit charge of electricity, detn. of Avogadro's number, C. T. R. Wilson's work on the paths of atoms and electrons, radioactive evolution of the elements, the "nucleus-atom" theory of at. structure ("Rutherford atom"), nuclear charges, Mosley's X-ray spectra, radioactive elements and the periodic system, and the distribution of electrons in the atom. While no new work is recorded, the paper is an excellent review of the whole subject of atomic constitution. E. B. MILLARD.

Preparation of anhydrous solids. W. R. G. ATKINS AND E. G. WILSON. *J. Chem. Soc.* 107, 916-8(1915); see *C. A.* 9, 1569. E. B. MILLARD.

Topic parameters and morphotropic relationships. WM. BARLOW AND W. J. POPE. Cambridge. *Phil. Mag.* 29, 745-9(1915).—Topic parameters have no significance in the description of morphotropy. The usual illustration of the function of the parameters in the variation from cubic NH_4I to tetragonal NMe_4I , in which one dimension remains unchanged, is erroneous, because the indices chosen for the description, (100) and (111), are not the simplest. When (110) and (101) are used the latter salt is pseudo-cubic and the three topic parameters undergo equal change. A table is given to show that alkyl substitution in NH_4 salts gives pseudo-cubic forms.

G. L. WENDT.

Construction of cubic crystals with theoretical atoms. A. C. CREHORE. Columbia Univ. *Phil. Mag.* 29, 750-75(1915).—Mathematical. G. L. WENDT.

Enantiomorphism of molecular and crystal structure. W. BARLOW AND W. J. POPE. *J. Chem. Soc.* 107, 700-2(1915); cf. *C. A.* 8, 3523.—Barker and Marsh (*C. A.* 8, 3897) have made the statements: "Any assemblage of points possessing no other screw axes save diagonal can only be endowed with optical activity providing the points themselves (that is, the mols.) are enantiomorphous," and that in the case of enantiomorphous grouping of non-enantiomorphous mols., "the arrangement of mols. must possess screw axes of symmetry." The first statement is untrue, for the system may be a complex one in which a number of different point spirals having a common axis are found interpenetrating. Sohncke, many years ago, stated that a number of interpenetrating point systems must be taken to represent the crystal structure in some cases, and the justice of the same assumption by B. and P. has been demonstrated by X-ray methods. If the second statement of B. and M. (above) implies that the existence of these axes is a geometrical necessity in all such cases, it is incorrect, for an enantiomorphous arrangement of non-enantiomorphous mols. is geometrically possible in any one of the 65 types of homogeneous arrangement discriminated by Sohncke. If the enantiomorphism of a crystal structure and the consequent optical activity are entirely traceable to an arrangement of points (centers of force) located by coincident movements

about screw axes, the configuration of a single component mol. is not enantiomorphous. This is in direct contradiction to Barker and Marsh. E. B. MILLARD.

Regular intergrowths of barium bromate crystals. G. AMINOFF. Stockholm. *Centr. Min. Geol.* 1915, 163-70.—Extensive crystallographic measurements were made on apparently twinned crystals of $\text{Ba}(\text{BrO}_3)_2 \cdot \text{H}_2\text{O}$. True twinning could not be established, the crystals being regular intergrowths with a parallelism of certain faces and approximate parallelism of important zones. E. T. WHERRY.

Optical rotatory power in lithium sulfate monohydrate. A. JOHNSON. Kiel. *Centr. Min. Geol.* 1915, 233-43.—A method of prepg. large homogeneous crystals is first described; it consists of immersion of nuclei in a satd. soln. in a specially constructed thermostat (figure given). The optical properties of crystals of $\text{Li}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ thus prepd. were studied in detail and the mean rotatory power per mm. detd. was $\alpha_D = 1^\circ 48' = 39'$. The crystals are monoclinic-hemimorphic; those which have the analogous pole of their pyroelectricity to the right are dextrorotatory, the others levorotatory. E. T. WHERRY.

Valence volume theory. T. V. BARKER. *J. Chem. Soc.* 107, 744-73(1915).—The paper is a critical exam. of the Barlow and Pope theory. LeBas' interpretation of Kraft's work (*C. A.* 1, 1118) has been shown (*C. A.* 8, 3523) to have no conclusive bearing on the subject of valence volumes. The alleged evidence which has been collected to support the theory is examd. from the crystallographic point of view, and B. concludes that "the data derived from angular measurements of crystals afford no ground for supposing that the theory is in accordance with the facts, and that the apparently satisfactory results obtained by the authors of the theory and their followers have been due to the subsequent application to the observed data of arithmetical operations, which are arbitrary and inadmissible, and might have been equally used to produce similar results from quite other assumptions." In Part I the laws of valency vol. are discussed; in Part II the methods are criticized in the light of crystallographic facts; Part III is devoted to detailed analysis for individual substances. E. B. MILLARD.

New researches on metallic clouds. V. A slag containing a manganese cloud. RICHARD LORENZ. *Z. anorg. allgem. Chem.* 92, 34-6(1915).—Describes a slag containing Mn in a highly dispersed condition forming a Mn cloud. Cf. *C. A.* 9, 2490.

GEORGE W. MORRY.

The general theory of corresponding states and the thermodynamic state-equation. G. VON KAUFMANN. Cambridge. *Phil. Mag.* 30, 146-62(1915).—A general equation is developed, $(\pi + 1/\Phi^2)(\Phi - 1) = \theta$, as an algebraic reduced form of van der Waals' equation. This is applied to several cases which involve no easily recognizable critical points and an attempt is made to calculate from the state-equation the relations connecting t , p and v in a 2-phase system. G. L. WENDT.

Experimental determination of the critical constants of oxygen, nitrogen, carbon monoxide, and methane. ETORRE CARDOSO. Geneva. *Arch. sci. phys. nat.* 39, 400-2(1915); cf. *C. A.* 8, 1045, 1147, 1896.—Temps. have been measured with a pentane thermometer, which was shown to be accurate when certain precautions were taken. The purity of the gases was controlled by isotherms of compression at different temps. while the respective vols. of the 2 phases were varied within wide limits. The following values were obtained as the means of several concordant expts.: N, crit. pressure 33.65 atms., crit. temp. -144.7° ; CO 34.60 atms., -137.7° ; O 49.30 atms., -118.0° ; CH_4 45.60 atms., -82.85° . Details will be given in a future paper. E. B. MILLARD.

Densities of the coëxisting phases of methane and of carbon monoxide. ETORRE CARDOSO. Geneva. *Arch. sci. phys. nat.* 39, 403-4(1915); cf. *C. A.* 8, 1896.—The method formerly used has been perfected. Using a Kuenen stirrer in the liquid phase,

and all precautions, the crit. d. for CH_4 was found to be 0.1623 and for CO 0.3110. The values were obtained by plotting and using rectilinear diameters. Exptl. details are not given.

E. B. MILLARD.

Criticism of Gurvich's hypothesis of a physico-chemical attractive force. N. A. KOLOSOVSKII. *J. Russ. Phys. Chem. Soc.* 47, 717-23(1915).—Gurvich's hypothesis of the existence of a new physico-chem. attractive force, different from purely phys. and purely chem. forces (cf. *C. A.* 8, 2090), is of no value for a better understanding of the phenomenon of soln. Phys. attraction operates between mols., and chem. between atoms. But between what entities does the new force act? G.'s special equations for calcg. the distribution of a substance between 2 adsorbents (or solvents) are perfectly arbitrary and entirely unnecessary. His only reason for inventing a new force is the disagreement he claims to have found between his exptl. data and the values calcd. from the formulas of Nernst and Freundlich. A careful recalcn. of these data by K. shows them to agree as well with these as with G.'s equations. In carrying out these calcns. K. observed that the distribution of either BzOH or valerician acid between benzine and floridin is given by the same formula: $y = 5.38p^{0.086}$, in which p is the conc. of the adsorbed in the adsorbing substances, and y is the variable in the equations of N. and F.

H. M. GORDIN.

Negative colloidal ferric hydroxide. FRANK POWIS. *J. Chem. Soc.* 107, 818-24 (1915).—By adding colloidal Fe(OH)_3 to a dil. soln. of NaOH of suitable conc. it may be changed from positive to negative, coagulation being prevented by mixing in this order. It may also be prepd. directly as a neg. colloid by allowing the Fe(OH)_3 particles to form in the presence of a dil. soln. of NaOH . The p. d. at the surface of a colloidal particle is due to the adsorption of ions from the soln., and its sign depends on whether the cations or anions are in excess in the layers nearest the particle.

E. B. M.

Ionization of bromine solutions of iodine trichloride. V. A. PLOTNIKOV AND V. E. ROKOTYAN. *J. Russ. Phys. Chem. Soc.* 47, 723-30(1915).—In support of their former statements (*C. A.* 7, 2148), P. and R. detd. the elec. cond. of ICl_3 in Br and in $\text{CH}_2\text{ClCO}_2\text{H}$ and found that the value of the dielec. const. of a solvent has nothing to do with cond. The explanation of the cond. in the present case is similar to that given in the article referred to. Solns. of ICl_3 in CCl_4 , SiCl_4 or CHCl_3 are almost devoid of cond.

H. M. GORDIN.

Displacement of metals by zinc in solutions of their salts. M. TZENTNERSHVER AND YUL. DRUKKER. *J. Russ. Phys. Chem. Soc.* 47, 528-36(1915).—A study was made of the velocity of displacement of Cu from solns. of CuSO_4 by Zn , using the equation: $k = 2.303p(\log C - \log c)/Ft$, in which k is the velocity const., v the vol. of the soln., C the initial conc. of CuSO_4 , c its conc. at the time t , and F the total area of the Zn . The detns. were made by rotating a Zn plate of definite dimensions in solns. of CuSO_4 of different concs. and detg. from time to time the amts. of CuSO_4 left unchanged. An exam. was also made of the time interval between the moment of immersion of the Zn plate into solns. of Ni , Co and Cu salts and the first appearance of these metals on the plate. The salts used were: CuSO_4 , NiCl_2 , NiSO_4 , $\text{Ni(NO}_3)_2$, CoCl_2 , CoSO_4 , and $\text{Co(NO}_3)_2$. The results given in tables may be summarized as follows: With Cu salts Zn reacts much more readily than with those of Ni or Co . With chlorides the reaction starts much earlier than with sulfates, while with $\text{Ni(NO}_3)_2$ or $\text{Co(NO}_3)_2$ Zn does not react at all, unless the conc. is very high; even then the ppt. is not the free metal but what seems to be its hydroxide (greenish in the case of $\text{Ni(NO}_3)_2$). The passivity of Zn towards $\text{Ni(NO}_3)_2$ and $\text{Co(NO}_3)_2$ cannot be due to NO_3 ions, since in solns. of both $\text{Ni(NO}_3)_2 + \text{K}_2\text{SO}_4$ and $\text{NiSO}_4 + \text{KNO}_3$ the Ni is pptd. by Zn , though in these cases the ppt. is greenish white. The action of Zn on solns. of Ni or Co salts is accompanied by an evolution

of gas (probably H produced by the Zn-Ni or Zn-Co couple). In the case of Ni salts the liberation of gas begins much earlier than in the case of Co salts, while in solns. of Cu salts Zn causes no evolution of gas at all. Comparing the lengths of time required to start the liberation of H from acids by Zn on the one hand, and of Ni, Co or Cu on the other, it is shown that in both cases there is a period of induction which is, however, much shorter in the liberation of the metals than in that of H. This is ascribed to the resistance of the layer of dielectric on the surface of the Zn which the H must pass in changing from the ionic to the mol. condition (cf. C. A. 8, 2834). In the case of the displacement of metals by Zn there are formed on the surface of the latter "local elements" (cf. Auren and Palmaer, *Z. physik. Chem.* 45, 182) which, having a very low resistance, facilitate the electrochem. interchange of metals. H. M. GORDIN.

Freezing point diagrams of formamide with water and the aliphatic acids and their bearing on the interpretation of viscosity measurements. S. ENGLISH AND W. E. S. TURNER. *J. Chem. Soc.* 107, 774-83(1915); cf. C. A. 8, 3258.—The curve formamide-H₂O proceeded to a V-shaped eutectic at -45° and about 43 mol. % formamide. A slight disturbance in the regularity of the curve on the H₂O side indicated the existence of a compd. HCONH₂·H₂O, the stability of which was limited. The HCONH₂·HCOOH curve had the usual form corresponding to a compd., 2 side branches and a convex center portion indicating HCONH₂·HCO₂H with a m. p. of 1.1°. This compd. was analyzed, and shown to consist of 1 mol. of each substance. In the system formamide-HOAc, the existence of a compd. HCO₂NH₂·2CH₃CO₂H was indicated; in propionic acid-HCONH₂ 2 maxima were found, one at 33% propionic acid, the other at 50% propionic acid; and in *n*-butyric acid-formamide a 4-branch curve indicating 2 compds. as with propionic acid. The expts. were made with a pentane thermometer and cooling baths of ether-CO₂ or ether-liquid air. Although maxima in viscosity curves may be due to compds., their formation is not always accompanied by viscosity maxima. These curves do not appear to differentiate between 3 compds. in a mixt., or to indicate the existence of more than 1 compd. The max. deviation from the law of mixtures does not show the true compn. of a compd. in all cases; in HCONH₂·HOAc the max. deviation lies at 50 mol. %, while the compd. contains only 33 mol. % HCONH₂. E. B. M.

New method of finding the second dissociation constants of dibasic acids. ASWINI KUMAR DATTA AND NILRATAN DHAR. Calcutta. *J. Chem. Soc.* 107, 824-7 (1915).—The method is based on the fact that a soln. of a normal salt of a strong base with a dibasic acid dissolves more CO₂ than the same vol. of H₂O at that temp. In the salt soln. hydrolysis occurs; the CO₂ forms HCO₃⁻ and H₂O. If *a* is the concn. of CO₂ dissolved in a given amt. of H₂O and *s* the concn. of CO₂ in a salt soln. of concn. *c*, the concn. of excess CO₂ = concn. HCO₃⁻ = concn. HX⁻, the concn. of the neg. radical of the salt = *c* - 2(*s* - *a*), and the second dissociation const. of the acid is, therefore, (assuming the H₂CO₃ to be a monobasic acid, and that the salt is 100% dissociated) $[H^+][X^-]/[HX] = \{a \times 3 \times 10^{-7}[c - 2(s - a)]\}/(s - a)^2 = K$. From expts. on several acids, the values for the second H⁺ were obtained as follows: tartaric acid 69.0, succinic 2.9, malonic 1.36, oxalic 31.0, fumaric 26.9, malic 9.03, phthalic acid 1.82. The values are for $K \times 10^8$ at about 25°, after correction for the degree of dissociation. E. B. MILLARD.

Electromotive forces in alcohol. VI. Absolute potentials by the capillary electrometer. EDGAR NEWBERRY. *J. Chem. Soc.* 107, 852-7(1915); cf. C. A. 9, 1000.—The unsatisfactory dropping electrode was replaced by a capillary electrometer in this series of expts. From 200 sets of data, 21 were selected as the most uniform, of which the mean was 0.483 volts for the potential for max. surface tension of Hg in a satd. alc. soln. of NaCl at 20°. The absolute potential of Hg in a satd. aq. soln. of NaCl at 20° was 0.481 v., a mean of 6 series selected from 50. In *N* aq. NaCl the value was 0.531 v.

and in 0.1 *N* 0.580 v. The temp. coeff. was +0.0008 v. per degree in 0.1 *N*, +0.0006 v. in *N*, and +0.0004 v. per degree in satd. aq. NaCl at 20°. These expts., and a similar series with NH₄Cl furnish strong support for Lapworth's theory that the abs. potential of a metal in a satd. soln. of a given salt is the same whether the solvent be H₂O or some other liquid, provided each ion involved has the same affinity for water as for the other solvent. The satd. soln. potentials are at least of the right order demanded by theoretical considerations, and are more reliable than the dropping-electrode values.

E. B. MILLARD.

Some aspects of the theory of acids. A. LAPWORTH. *J. Chem. Soc.* 107, 857-68 (1915); cf. Newbery, preceding abst.—During some of the most remarkable changes in activity which an acid undergoes (on account of changes in the medium or the addition of substances of a basic character), the parallelism between catalytic activity and the power of forming salts with weak bases is complete (so far as the ionized part of the acid is concerned). Two solns. may be regarded as being equal in "acidness" when they affect a given weak base under fixed conditions in the same manner and to the same extent. Two solns. are equally "acidic" with regard to the non-ionized acid when the thermodynamic potential of the non-ionized acid is the same in the 2 solns., and equally "acidic with respect to H ions" when the thermodynamic potentials of these ions are identical in the solns. The fact that the transference numbers of Na⁺, NH₄⁺, K⁺, Ag⁺, NO₃⁻, Cl⁻, etc., are the same in alc. as in H₂O, indicates either that the ions have no affinity for either solvent or that the affinities are approx. the same for both solvents. If this is true, the single potential differences between Hg and solns. satd. with both HgCl and NaCl should be the same in alc. and aq. solns., as found by Newbery. The transference number of H⁺ ion in alc. soln. at 25° has been detd. in the app. in Ostwald-Luther (3rd ed., p. 504), using a copper coulometer and analyzing only the cathode side. From the mean of 4 expts. at 0.1110 *N* and 1 at 0.8360 *N*, the value 0.31 was given. The individual values varied from 0.32 to 0.29. From a similar series in which the analysis was made from conductivity, 0.37 was obtained. The value for Li ion in abs. alc. at 25° was found to be 0.63 in 0.2 *N* and 0.65 in 0.04 *N* LiCl.

E. B. MILLARD.

Diffusion of gases at low pressures made visible by color effects. C. T. KNIPP. *Science* 42, 93-4 (1915).—If a very small quantity of illuminating gas is introduced into one end of a long discharge tube contg. a Geissler vacuum during discharge, a greenish white color appears at once. The color diffuses slowly toward the other end, becoming paler as it progresses. At the end of 3 or 4 min. the color throughout is grayish. The reverse expt., the diffusion of air into the illuminating gas at low pressure, may be shown immediately in the same app. (without removing the H₂O vapor, etc., formed) by adding a very small quantity of air at low pressure. The resulting orange-red color characteristic of air, with its slow diffusion through the gray tint of the illuminating gas, is readily seen.

E. B. MILLARD.

Binary and ternary systems of the nitrates of the alkali and alkaline earth metals. W. D. HARKINS AND G. L. CLARK. *J. Am. Chem. Soc.* 37, 1816-28 (1915).—F. ps. of 81 mixtures of NaNO₃, KNO₃ and Ba(NO₃)₂ have been detd. in an app. similar to that of Menzies and Dutt with some added refinements. Twelve detns. in the system NaNO₃-KNO₃-Sr(NO₃)₂, 11 in the system KNO₃-LiNO₃, and 8 in the system KNO₃-LiNO₃-Ba(NO₃)₂ have also been made. Temps. up to 250° were measured with a Gerhardt Hg thermometer, from 250 to 350° with a N-filled Hg thermometer, and above 350° with a Pt resistance thermometer which was used to calibrate the other instruments. The f. p. of Ba(NO₃)₂ was accurately detd. as 595.53°. The usual triangular diagrams have been drawn, together with plane figures for temp.-compn.

E. B. MILLARD.

Relation between the diagrams of fusion and viscosity of binary systems. I. KURNAKOV, D. KROTKOV AND M. OKSMAN. *J. Russ. Phys. Chem. Soc.* 47, 558-88 (1915).—A comparison was made between the diagram of fusion and that of viscosity of each of the following binary systems: $C_{10}H_8$ and $PhNO_2$, $m-C_6H_4(NO_2)_2$ or $1,3,5-C_6H_3(NO_2)_3$; $SbCl_3$ and C_6H_6 , $C_{10}H_8$, Ph_3CH_2 or Ph_3CH ; $SbBr_3$ and Ph_3CH , Ph_3CO , toluene or $PhNH_2$. The viscosity diagrams were detd. by the authors, while the fusion diagrams were taken from the literature. The results, given in numerous tables and curves, may thus be summarized: The definite compds. of $C_{10}H_8$ with the NO_2 derivs. of C_6H_6 are capable of existence in solid condition only, being more or less completely decompd. when liquefied. Hence their formation is revealed on the fusion diagrams, but not on the viscosity diagrams, while in the liquid systems of the Sb halides the interaction of the components is shown on both the fusion and the viscosity diagrams. In these systems there is an intimate relation between the max. on the viscosity diagrams and the dystectic point on the corresponding fusion diagrams. The viscosity diagrams of these systems reveal very readily the existence of compds. of irrational type whose max. are gradually displaced towards the rational ordinate by lowering the temp., while raising the temp. has the opposite effect. This is ascribed to partial dissociation of the rational compds. by heat. In the system $SbBr_3-Ph_3CH$ the viscosity diagram reveals the existence of a compd. $SbBr_3 \cdot CHPh_3$, which is not shown on the fusion diagram at all. This is probably due to the very viscous $SbBr_3$, being unfavorable to the crystn. of the compd. H. M. GORDIN.

Application of the conception of expansibility tension to the theory of hydrates. L. GAY. *J. chim. phys.* 13, 33-51(1915); cf. *C. A.* 8, 853; 9, 985.—G. discusses "expansibility" again, and applies it to a mathematical discussion of the equil. of 2 hydrates, and the stability of a hydrate. E. B. MILLARD.

Effect of temperature on the heat evolved in certain reactions. J. W. MELLOR. *J. chim. phys.* 13, 52-4(1915).—In addition to the type of reaction which is endothermic at low temps. and exothermic at higher temps., another type is possible, in which the change is from exo- to endothermic. Thus, if a polyatomic substance dissociated in stages $A_n \rightarrow A_{n-2} \rightarrow A_{n-4}$, etc., reacted with a diatomic substance or another one which also dissociated in stages, the heats of formation of the compd. at higher and higher temps. might change sign. No example has been given E. B. MILLARD.

Heat of formation and polymerization of some oxides and determination of the heat of combustion of water by fusion with sodium peroxide. W. G. MIXTER. *Am. J. Sci.* 40, 23-32(1915); cf. *C. A.* 9, 1437.—Pptd. $CaSO_4 \cdot 2H_2O$ was mixed with S and Na_2O_2 , and the heat effect on fusion detd. CaO gives no heat effect on fusion with Na_2O_2 ; the other effects were computed from existing data. The heat of combination of $CaSO_4$ with $2H_2O$ was found to be 4800 cal.; for $MgO + H_2O$, 9400 cal. The statement (*C. A.* 7, 2888) that the heat effect of each of the 3 atoms of O in Fe_2O_3 is the same has been modified. Part of the heat of formation of Fe_2O_3 at high temps. is due to the formation of complex mols., so that the heat effect of the third O is considerably less than that of the first one. For the heat of condensation of TiO_2 on ignition the value 3000 cal. was found. TiO_2 contg. 2.2% H_2O evolves between 3 and 6 Cal. on ignition. SiO_2 polymerizes at high temps. with little heat effect. If the hydroxide is regarded as formed by the union of H_2O with unpolymerized mols., the following values may be derived: $ZnO + H_2O = 2.4$ Cal., $MnO + H_2O = 4.0$ Cal., $FeO + H_2O = 4.0$ Cal., $CdO + H_2O = 8.7$ Cal. (approx.). The first values may be too low since the heats of formation of the oxides may include a small heat effect due to polymerization at high temps. E. B. MILLARD.

Changes of phase under pressure. II. New melting curves, with a general thermodynamic discussion of melting. P. W. BRIDGMAN. *Phys. Rev.* 6, 1-33(1915); cf. *C. A.* 8, 2295.—Details are given of new expts. on CHBr_3 , SiCl_4 , $\text{C}_6\text{H}_5\text{Cl}$, $\text{C}_6\text{H}_4\text{Br}$, benzophenone, *p*-nitrophenol, *p*-toluidine and Me oxalate. In most cases the m. p., compressibility, dr/dP , latent heat of melting and change of energy have been calcd. for each 1000 kg. per sq. cm. up to 8000 kg. Diagrams showing the relation of pressure to temp., and to ΔV have been drawn. The same data have been taken on Bi up to 12000 kg. per sq. cm. The following substances were examd. for new solid forms without result: Menthol, anethole, C_{10}H_8 , acetophenone, and SbI_3 , though some melting data were collected. The work on Na has been recalcd. for new values of ΔH and ΔE . The thermodynamic discussion is to appear in the next installment of the paper.

E. B. MILLARD.

Mechanism of the chemical action of electrical discharges. Role of ionization. E. BRINER. *J. chim. phys.* 13, 18-32(1915); cf. *C. A.* 9, 880.—Using the same app. as before, but adding a pair of auxilliary electrodes connected to a Wulf electrometer to measure ionization, the combination of N with H or O has been investigated. As before, the % NH_3 was a max. at 100 mm. pressure. The action of the discharge may be thermal, elec. or photochem., but the latter effect was absent in the fixation of N. From these expts. B. concludes that the action of the arc is almost entirely thermal in nature, not ionic. The heat of formation of NH_3 from the atoms was calc. to be 300 cal.

E. B. MILLARD.

Application of integral equations to the theory of electrolysis. KURT SCHELLENBERG. *Ann. Physik* 47, 81-127(1915).—Wholly mathematical.

E. B. MILLARD.

The influence of silent electric discharge upon mixtures of hydrogen and nitrogen. M. LE BLANC. Univ. Leipzig. *Ver. K. Sach. Wiss. Leipzig* 66, 38-63(1914).—The amt. of NH_3 formed by the elec. discharge through H and N depends upon the size of the discharge tube, c. d., H residue, and frequency of exciting current, and is an extremely complicated function of these variables. The chem. reaction does not obey the law of mass action. Cf. *C. A.* 8, 3520.

PAUL D. FOOTE.

Kinetics of chemical reactions. XI. E. I. ORLOV. *J. Russ. Phys. Chem. Soc.* 47, 624-41(1915).—It was shown in a series of former articles on this subject that the usual equation for monomol. reactions must be modified whenever secondary reactions influence the progress of the main reaction. A case in point is esterification in presence of acid catalyzers. In most cases of esterification under such conditions the secondary reaction consists in the liberated H_2O uniting with some of the H ions of the catalyzer to form unstable H_2O mols., while in other cases it may have a more complex nature. The modified equation to be used will, therefore, depend upon the character of the secondary reaction. In the light of these considerations, O. examd. the investigations of Kailan (*C. A.* 8, 607, 2701), Nernst and Homan (*Z. physik. Chem.* 71, 379) and Zal'kind and Pishchikov (*C. A.* 9, 2067) and found that his equations give much more concordant values for the velocity consts. than the equation used by these authors. As an example of a secondary reaction of a complex nature the esterification of malic acid in presence of HCl as catalyzer (K., l. c.) may be mentioned. Here there are 3 reactions involved: formation of ester, substitution of Cl for OH, and regeneration of HCl with formation of $(:\text{CHCO}_2\text{R})_2$. Something similar takes place in the decomp. of bromosuccinic acid (Muller, *Z. physik. Chem.* 41, 483) where both ions of the liberated HBr enter into reaction with the fumaric acid produced. Numerous tables and calcs. illustrate the article.

H. M. G.

The kinetics of photochemical reactions and the law of radiation. A. SCHIDLOV. Genève. *Arch. sci. phys. nat.* 38, 97-112(1914).—It is postulated that in a photo-

chem. reaction the exciting radiation acts only on certain mols. which are the resonators. If a mol. of this kind goes from a modification without the power of resonance to a modification possessing this property, the energy absorbed in the transformation is a definite known function of the frequency of the exciting radiation. Further, the velocity of the photochem. reaction for each kind of active mol. is a function of the frequency and the mean energy of the resonator. With these assumptions the radiation laws, such as Planck's, and the equation of photochem. equil. are derived. The paper makes use of the quantum theory of emission, and the involved mathematic development does not permit a satisfactory abstract.

PAUL D. FOOTE.

The halogen-oxygen compounds. IX. Kinetics of the bromate-bromide reaction. A. SKRABAL AND S. R. WEBERITSCH. *Monatsh.* 36, 211-35(1915); cf. *C. A.* 8, 1533, 3736; 9, 996; and following abstr.—The kinetics of the reaction $\text{BrO}_3^- + 5\text{Br}^- + 6\text{H}^+ = 3\text{Br}_2 + 3\text{H}_2\text{O}$ was investigated by several methods. It was shown that (1) the velocity is proportional to the first power of BrO_3^- and Br^- and to the second power of H^+ ion concn.; (2) the velocity constant for 25° is of the order of magnitude of 200; (3) the temp. coeff. is 2; (4) Cl^- ion accelerates the reaction. The laws governing the temp. coeffs. given in Part VIII were proven for the general halogen reaction: $\text{XO}_3^- + 6\text{Y}^- + 6\text{H}^+ = \text{X}^- + 3\text{Y}_2 + 3\text{H}_2\text{O}$.

E. SCHRAMM.

Halogen-oxygen compounds. X. Kinetics of the formation of bromates from bromine. ANTON SKRABAL AND S. R. WEBERITSCH. *Monatsh.* 36, 237-56(1915); cf. preceding abstr.—The kinetics of the reactions $3\text{Br}_2 + 6\text{OH}^- = 8\text{Br}^- + 3\text{H}_2\text{O} + \text{BrO}_3^-$ and $3\text{Br}_2 + 6\text{OH}^- = 5\text{Br}^- + \text{BrO}_3^- + 3\text{H}_2\text{O}$ have been investigated. The velocity of bromate formation increased with the concn. of Br_2 and of OH^- and decreased with increasing concn. of Br^- . Values of the exponent of conc. varied with the speed of the reaction. Neutral salts retarded the reaction. The following relations also appeared probable: $-d(\text{Br}_2)/dt = k_1(\text{OH}^-)(\text{Br}_2)^{1/2}/(\text{Br}^-)^2$, or $-d(\text{Br}_2)/dt = k_1'(\text{OH}^-)(\text{Br}_2)/(\text{Br}_2)^2$ for the rapid reaction and for the slow reaction $-d(\text{Br}_2)/dt = k_2(\text{OH}^-)^4(\text{Br}_2)^{1/2}/(\text{Br}^-)^2$, or $-d(\text{Br}_2)/dt = k_2'(\text{OH}^-)^4(\text{Br}_2)^2/(\text{Br}^-)^4$. The temp. coeff. of the slower reaction in a monophosphate-biphosphate soln. was of the order of 17. From the velocity of the rapid reaction and that of $\text{HBrO} + \text{OH}^- = \text{BrO}_3^-$ the equil. Br -hypobromite can be calcd., and from the slower reaction and $\text{BrO}_3^- + \text{Br}^- + \text{H}^+ = \text{Br}_2$ the Br - BrO_3 equil. can be calcd.

E. B. MILLARD.

Energy exchange during photochemical processes in gases. V. Absorption of ultraviolet radiation by oxygen. E. WARBURG. *Sitzb. kgl. preuss. Akad.* 1915, 230-42; cf. *C. A.* 8, 613.—The previous work has been extended. The absorption of ultraviolet radiation by O depends on the pressure and wave length, since the deviation from Einstein's law of equivalents was found to be greater in the ozonization of O by $\lambda = 0.209 \mu$ than for $\lambda = 0.253 \mu$. Expts. were made on 95% O_2 for both of these wave lengths from $p = 27.5$ to $p = 392.5$ kg. per sq. cm. Neither the law of Beer nor that of Liveing and Dewar was satisfied, though the deviations were greater for Beer's law.

The specific heat (c_p) of superheated steam for pressures of eight to ten atmospheres and at saturation temperatures to 380° . O. KNOBLAUCH AND A. WINKLER. *Z. Ver. deut. Ing.* 59, 376-9, 400-5(1915).—The manner of conducting the test and the arrangement of app. used in the detn. were the same as described in *C. A.* 8, 610. The

detn. with steam passing through the app. is supplemented by a detn. made without steam passing; by this means the fraction of energy lost by radiation and conduction, while superheating the steam, is detd. The exptl. data obtained are recorded in the form of curves and tables. The results confirm the previously found data (*loc. cit.*) that c_p increases with increasing pressures, and in the case of increasing temps. above satn. pt. at first decreases, then later increases. The c_p isobars for 2 to 8 atms. in the proximity of satn. temps. are low in comparison with those previously published.

H. R. GUNDLACH

Pole effects in the iron arc. C. E. ST. JOHN AND H. D. BABCOCK. *Proc. Nat. Acad.* 1, 295-8(1915); cf. C. A. 9, 1424.—The pole effect for several lines grouped near λ 4085.14, λ 4766.41, λ 5528.14 and λ 6350, and the pressure shift per atm. have been detd. The pressure displacements varied as the cube of λ , but there was no apparent relation between λ and the pole effect. Emphasis has been placed upon the necessity of considering the pole effect in the redetn. of the wave lengths in international units. The wave lengths of these sensitive lines are not affected by a wide variation of density of the radiating vapor nor by changes of temp. over the range 2100 to 2600°. For the lines considered the pole effect does not occur *in vacuo*, and in so far appears independent of elec. conditions. Unless the pressure changes in certain definite ways with the wave length, the pole effect cannot be explained as a pressure effect.

Measurements of the spark spectra of the platinum metals: ruthenium, rhodium, palladium, iridium and platinum in the extreme ultraviolet. GUSTAV KAIL. *Sitzb. K. Akad. Wiss. Wien* 123, II A, June, 1914, 36 pp.—By the aid of known lines a dispersion curve was prepd. for the quartz spectrograph used. The shortest wave lengths measured for the Pt metals were as follows: Ru 1874.94 Å, Pt 1866.46 Å, Pd 1858.51 Å, Ir 1852.21 Å. A total of 1071 lines, of which 690 were previously unknown, has been measured.

E. B. MILLARD.

Application of interference methods to the study of the origin of certain spectrum lines. T. R. MERTON. *Proc. Roy. Soc. London (A)* 91, 421-31(1915).—In the case of radiations produced at low pressures, the limiting order of interference at which fringes may still be visible is given by the relation $N = K\sqrt{M/T}$, where N is the limiting order of interference, K a const., M the at. wt. of the luminous particle, and T the abs. temp. A convergent beam of light was thrown on the plates of a Fabry and Perot sliding interferometer and the ring systems were focused by means of an achromatic lens on to the slit of a large Hilger constant deviation spectroscope, each line thus appearing as a narrow strip of a ring system. The interferometer plates were slowly separated until a point was reached at which the fringes were just visible. From the separation of the plates at this point the value of N could be calcd. The value adopted for K was 1.22×10^4 (cf. Buisson and Fabry, *J. physique* 2, 442(1912)). Expts. on the g , H and K lines of Ca were not satisfactory, but a value of $N_{\text{Ca}} = 189259$ was obtained, from which $T = 1662^\circ$ abs., a value which appears to be too low for the temp. of the vacuum arc. From the H line, $T = 3100^\circ$ abs., which seems to show that in the g line M should be 80, i. e., the Ca_2 mol., while the H line is due to Ca atoms. The Sr lines λ 4607 and λ 5535 are strictly analogous to the g line of Ca. For λ 4606 (Sr), fringes were observed which, if due to Sr atoms, would give 834° as an upper limit for the temp. of the Sr arc. The molecules must be concerned in the production of this

radiation and of λ 5535. The red spectrum of A, for λ 4511, gave fringes corresponding to $T = 335^\circ$ abs., and the blue spectrum (excited by a rather weak condensed discharge) gave $T = 7400^\circ$ abs., an inadmissible value. E. B. MILLARD.

Band spectrum associated with helium. J. W. NICHOLSON. *Proc. Roy. Soc. London (A)* 91, 432-9(1915); cf. Fowler, *C. A.* 9, 1426.—In the He spectrum the approx. superposition of 2 series with the same limit but with very different modes of convergence among their coeffs. appears to be the cause of the unusual character of the doublet separations. A formula of the proper generalized Rydberg type has been calcd. from the first 4 lines of a rather simple series which gives a limit almost exactly that obtained by Fowler from the simple series, which he concluded must be nearly correct. The paper gives further support to Fowler's conclusions that the heads of the bands in the band spectrum of Goldstein and Curtis follow ordinary line-series laws, by showing that the doublet separations tend to zero at the limit of the series. Both the doublet series isolated by Fowler are strictly analogous to principal series in line spectra. The generalized Rydberg formula gives the most suitable representation of these series as well as of line series. E. B. MILLARD.

Enhanced series of lines in spectra of the alkaline earths. W. M. HICKS. *Proc. Roy. Soc. London (A)* 91, 451-63(1915). E. B. MILLARD.

Extension of the spectrum beyond the Schumann region. THEODORE LYMAN. *Proc. Nat. Acad.* 1, 368-71(1915).—By using a vacuum spectroscope contg. a concave diffraction grating arranged in such a manner that the light path from the source to the plate was wholly in gas, and using purified He at 3 mm. pressure, the spectrum has been extended from Schumann's limit of λ 1230 Å to λ 600 Å. Expts. on H established the line at 1216 Å which forms the first member of series predicted by Ritz, and the next 2 members of this series, λ 1026 and λ 972 Å. The region between λ 600 and X-rays (λ about 1 Å according to Bragg) is still to be explored; the present app. seems adapted for part of the region at least. E. B. MILLARD.

Dissociation spectra in the visible region and in the ultraviolet. II. Ultimate rays in general. A. DE GRAMONT. *Ann. chim.* 3, 269-87(1915); cf. *C. A.* 3, 2900. E. B. MILLARD.

Rotatory power. J. MINGUIN. *Ann. chim.* 3, 367-94(1915); cf. *C. A.* 8, 3036, 3288.—Report on a large number of expts. on rotatory power in homologous series, influence of the solvent, etc. The paper is a résumé of work which has already been published. E. B. MILLARD.

The number of electrons concerned in metallic conduction. G. H. LIVENS. Sheffield. *Phil. Mag.* 30, 105-12(1915).—A mathematical paper showing H. A. Wilson's theory (*C. A.* 5, 2463) to be inadequate. G. L. WENDT.

Frictional electricity on insulators and metals. W. M. JONES. Univ. Wales. *Phil. Mag.* 29, 261-74(1915).—Evidence is given that frictional electricity is an effect of a different order from that of contact electricity. Exptl. results are in fairly good agreement with the hypothesis that the rubbing friction has the effect of removing electrons from either the rubber or the specimen rubbed at a rate proportional to the rate of rubbing. It is shown that on this theory the frictional electricity reaches a const. max. value when the generation of charge is compensated by the leakage. A. T. CAMERON.

Conduction of electricity through metals. J. J. THOMSON. *Phil. Mag.* 30, 192-202(1915).—If atoms contain electrical doublets which, under the action of an electrical force, tend to arrange themselves so that their axes fall in a polarized line, conduc-

tion takes place when the electrical forces of the polarized atoms can abstract electrons from any atom and pass them on to its neighbor, and so form a chain. The polarized state is easily broken down by the rotation of the atoms. But at very low temps., where the kinetic energy of the atoms is very low, the polarized state persists after the electric or magnetic exciter is removed, and the current may continue indefinitely, as has been found experimentally at the temp. of liquid He by K. Onnes (*C. A.* 8, 2294, 3264). G. L. WENDT.

Energy of a moving electron. LEIGH PAGE. *Am. J. Sci.* 40, 116-28(1915); cf. *C. A.* 8, 3256.—The energy of a Lorentz electron moving with const. velocity has been calcd. by 3 different methods, and the expressions for this energy have been compared. The first method consists in finding the elec. and magnetic energies of the electron's field; the second consists in subjecting an electron which is at rest relative to the observer to an infinitesimal force for an infinite time. In this way a finite velocity is imparted to the electron without any finite radiation of energy; hence the sum of the initial electrostatic energy of the electron, the work done by the force in accelerating it and the work done by the ether pressure in producing the progressive contraction of the electron as its velocity relative to the observer increases, gives the energy of the electron. Starting with an uncharged moving electron, an infinite number of shells of infinite radius, each carrying an infinitesimal charge, are shrunk down to the radius of the electron, and the energy calcd. from the sum of this work and that done in maintaining the velocity of the spheres. This work was found to be equal to that of the magnetic energy of the field, but to differ from the expression for the kinetic energy peculiar to Einstein's relativity dynamics. E. B. MILLARD.

An atomic model with a magnetic core. H. S. ALLEN. King's Coll., London. *Phil. Mag.* 29, 714-24(1915).—An at. model is suggested consisting of a ring or rings of electrons surrounding a central core, having a radius considerably greater than the nucleus of the Rutherford atom and in consequence capable of producing appreciable magnetic forces in its vicinity. The total charge of the core must be equal to Ne , where N is the at. number. The magnetic moment of the core arises from the orbital motion of the discrete electrified particles (α particles, β particles, H nuclei or positive electrons) of which it is composed. The diamagnetic properties of the atom arise mainly from the external electrons revolving in orbits whose radius is of the order 10^{-8} cm. The magneton is regarded not as an independent entity, but as a unit convenient for measuring magnetic moments introduced in consequence of the principle of the constancy of angular momentum. A. T. CAMERON.

Negative thermionic currents from tungsten. K. K. SMITH. Princeton Univ. *Phil. Mag.* 29, 802-22(1915).—There is a marked increase in the current after the filament has been heated for some time above 2700° K. in a good vacuum, owing to the removal of oxides and impurities from the surface. The state then attained is permanent unless gas is liberated inside the lamp from excessive heating or water vapor is introduced. The formula $i = aT^{1/2}e^{b/T}$, where i is the satn. current, and a and b are consts., is shown to hold for values of T from 1050° K. to 2300° K., giving a variation in i of 10^{12} . G. L. WENDT.

A new type of ion in the air. J. A. POLLOCK. Univ. Sydney. *Phil. Mag.* 29, 636-46(1915).—A description is given of certain characteristics of an ion in the air with a mobility intermediate between that of the small gas ion and that of the large ion of Langevin. The mobility is found to depend on the water-vapor pressure rather than on the relative humidity. Both the intermediate and large ions exist in the air at the same time provided the vapor pressure is below 17 mm. Above this pressure only the large ions are found. It seems probable that the intermediate ion consists of a rigid nucleus enveloped by a dense atm. of water vapor. The mass of the ion becomes

greater as the vapor pressure increases until at a critical pressure the adsorbed fluid assumes the liquid state, and the aggregation develops, by the rapid condensation which ensues, into the large ion of Langevin. The intermediate and large ions thus appear to form a striking illustration of Trouton's discovery (*C. A.* 2, 11) of the 2 modes of condensation of water vapor on rigid surfaces. A. T. CAMERON.

The larger ions in the air. J. A. POLLOCK. Univ. Sydney. *Nature* 95, 286-8 (1915); cf. *C. A.* 9, 1430 and preceding abstr. W. H. ROSS.

Remarks regarding the series spectrum of hydrogen and the constitution of the atom. L. VEGARD. Univ. Christiania. *Phil. Mag.* 29, 651-5(1915).—By a modification of Allen's reasoning (*C. A.* 9, 753) a similar result is obtained which allows a const. difference of momentum to be maintained between the outer and inner systems of the atom. A. T. CAMERON.

Radiation from an electric source and line spectra. The hydrogen series. I. SILBERSTEIN. Univ. Rome. *Phil. Mag.* 29, 709-14(1915). A. T. CAMERON.

Substances possessing anomalous dispersion and molecular rotatory power. II. Verification of the theories of light propagation in active absorbing media. G. BRUHAT. *Ann. phys.* 3, 417-89(1915); cf. *C. A.* 9, 2178.—Theoretical. E. B. M.

Correction of the Curie-Langevin law of magnetization for molecular distances. E. A. HOLM. *Ann. Physik* 47, 1-48(1915).—Theoretical. An expression for the mean kinetic energy of a gas mol. in a magnetic field at the moment of impact has been derived and introduced into the Maxwell distribution law. Assuming the approximate expression of O. E. Meyer for the mean free path corresponding to a given velocity, a correction term has been computed for the Curie-Langevin law which is a function of the mean free path, both moments of inertia, and the mass of the mol. The mathematical treatment cannot be briefly abstracted. E. B. MILLARD.

3. RADIOACTIVITY.

WILLIAM H. ROSS.

The variation with meteorological conditions of the amount of radium emanation in the atmosphere, in the soil gas, and in the air exhaled from the surface of the ground at Manila. J. R. WRIGHT AND O. F. SMITH. *Physic. Rev.* [2] 5, 459-82(1915).—Using the method of absorption by coconut charcoal the Ra Em content of the air was detd. by comparison with the Ra Em furnished by a standard Ra soln. for a period of 13 months. The mean value in g. of Ra equiv. to the Em per cu. m. is 71.0×10^{-12} , with a max. in January about 10 times the minimum in July. High values correspond to low rainfall and low wind movement, and *vice versa*; but there is no connection with atmospheric pressure, humidity, or direction of the wind. The same relations are found in the diurnal variations, where the night value is 3.31 times the day value. After heavy rains the Em exhaled from the soil decreased by 60%. Such a decrease is accompanied by a large increase in the Em content of the soil gas at a depth of 30 cm., but at 70 cm. and 120 cm. there is little variation with the weather. At 120 cm. the mean value is 304.5×10^{-9} g. per cu. m., about 7 times the value at 30 cm.

G. L. WENDT.

A modified variable condenser for use with the quadrant electrometer. HARRY CLARK. Harvard Univ. *Physic. Rev.* [2] 6, 43-5(1915).—The ionization current in radioactive measurements is here compensated by varying the capacity of a condenser, composed of a pile of semicircular plates mounted on a central rotating shaft, and maintained at a fixed potential. Another set of such plates, mounted on the same shaft but insulated from the first, compose actually another condenser which is kept earthed and which rotates into the position of the first when that is turned. The total capacity is thus unchanged and measurements can be made which allow the spot of light to drift some distance to one side of the zero at the start and at the end. By changing the potential the instrument is capable of a wide range of charge. G. L. WENDT.

Exchange of atoms between solid and liquid phases. G. v. HEVESY. Vienna. *Physik. Z.* 16, 52-5(1915).—The question of the exchange of atoms between a solid and liquid phase, for example between metallic Pb and a soln. of $\text{Pb}(\text{NO}_3)_2$, may be examd. by mixing with the Pb salt its radioactive isotope, Th B, and detg. how much of the Th B passes into the other phase in a given time. For the case, $\text{Pb} \mid \text{Pb}(\text{NO}_3)_2$, the exchange is very rapid, caused by local currents, Pb going into soln. at some points and depositing out at others. The exchange between a layer of PbO_2 and a $\text{Pb}(\text{NO}_3)_2$ soln. is much slower and amounts in the case of a 0.001 *N* soln. to an exchange in 1 min. of $\frac{1}{2}$ of the mol. layer of PbO_2 . Ten min. are required for the exchange of the entire layer. In the employment of the layer of PbO_2 one approaches much nearer to the ideal case of "kinetic exchange," that is, under conditions of thermodynamic equil. between the 2 phases, than in the case of the easily attacked metallic Pb layer. S. C. LIND.

The question of isotopic elements. Reply to K. Fajans. G. v. HEVESY AND F. PANETH. Vienna. *Physik. Z.* 16, 45-51(1915).—In spite of the thermodynamic considerations which Fajans (*C. A.* 9, 1149) has brought forward to show the untenability of the views advanced by the authors (*C. A.* 9, 175) regarding the mutual interchangeability of isotopic elements, the latter are prepared to reiterate their contentions in the main, that the expression for ionic conc. in the Nernst formula for e. m. f. should be understood as referring to the sum of the concs. of isotopic ions, and that isotopes can fully replace each other in all types of chem. reactions. The authors agree with Fajans in considering different isotopes as thermodynamic individuals, but the only practical objection raised by Fajans to their electrochem. expts., viz., that an isotopic elemental electrode cannot possess a definite e. m. f. toward the ions of a different isotope in soln., is now claimed to have been disproved by the following expt.: An electrode of PbO_2 exhibits exactly the same potential toward 2 different solns. of the same mol. conc., the one containing $\text{Pb}(\text{NO}_3)_2$ and the other $(\text{RaG})(\text{NO}_3)_2$, although the time of contact was by no means sufficient for equil. to have been established between the solid and liquid phases, a condition which Fajans claimed is necessary for the establishment of a definite potential. S. C. LIND.

Stereoscopic photography by Röntgen rays. BÉLA ALEXANDER. *Physik. Z.* 16, 141(1915).—A description and reproductions of X-ray photographs of a roll of wire netting which bring out the effect of a third dimension with great distinctness. S. C. LIND.

Radioactive and chemical analysis of the uranium pitchblendes of Joachimsthal. A. BECKER AND P. JANNASCH. Univ. Heidelberg. *Jahrb. Radioakt. Elektronik* 12, 1-34(1915).—Besides the detn. of the Ra/U ratio in pitchblende, the authors have also made in duplicate a complete analysis of pitchblende, having in mind its possible future application in investigating the question of the genetic relation of other elements than Ra and U. To this end a sample of pitchblende of great purity and homogeneity was chosen. The chem. analyses were carried out by J., and the radioactive measurements by B. The chem. sepsns. are described in detail, and much weight is laid upon the use

of the hydroxylamine method for the sepn. of Fe and U. The results of the analyses are as follows: U_2O_5 76.41, 76.82; Fe_2O_3 4.15, 4.00; PbO 4.67, 4.63; Bi_2O_3 0.63, 0.67; As_2O_3 0.99, 0.82; Sb traces; ZnO 0.08, 0.22; MnO 0.13, 0.04; SiO_2 5.57, 5.07; CaO 3.03, 2.45; MgO 0.13, 0.19; K_2O 0.16, 0.28; Na_2O 1.21, 1.19; rare earths 0.43, 0.52; H_2O 3.25; S 1.37, 1.15%. The Ra measurements were carried out in an emanometer (*C. A.* 5, 604) which was calibrated by means of standard solns. prepared from Ra salts which had been compared with the Ra standard of the Radium Inst. of Vienna. The accumulation method from zero was used for pitchblende both in HCl and HNO_3 solns. and also in a fusion method with Na_2CO_3 - $LiCO_3$ mixt. The av. Ra/U ratio found by the soln. method was $3.383 \times 10^{-7} \pm 1\%$; and by the fusion method, $3.415 \times 10^{-7} \pm 0.7\%$. The latter value is about 2% higher than that found by Heimann and Marckwald (*C. A.* 7, 3269). S. C. LIND.

Extraction and separation of the radioactive constituents of carnotite. H. M. PLUM. *J. Am. Chem. Soc.* 37, 1797-1816(1915).—Several of the commercial methods for extracting U and V from carnotite ores have been examined and modified so as to apply to mixtures of carnotite and vanadiferous silicates. No single operation was found to remove V and U thoroughly. U was removed by boiling with Na_2CO_3 pptd. as $UO_2CO_3 \cdot 2Na_2CO_3$ by concn. of the soln., and the Na_2CO_3 recovered. Ra, Act and Radio-Pb were extracted from the residue insol. in Na_2CO_3 by HCl; the portion of Ra still undissolved was removed by HNO_3 and the Io was finally extracted by dil. H_2SO_4 and pptd. with Ce. HNO_3 was not a suitable reagent for primary treatment of carnotites. H_2SO_4 completely extracted U and V, but left the radioactive constituents in the residue. Most of the Ra was in the HCl extract, and about 90% of the total Ra was obtained by extracting with both HCl and HNO_3 ; this yield was increased about 2.7% by pptg. more $BaSO_4$ in the acid filtrates. E. B. MILLARD.

A method of calculating the absorption coefficients of different substances for homogeneous X-radiation. H. MOORE. *King's Coll. Proc. Phys. Soc. London* 27, 432-8(1915). Discussion, 438-9; see *C. A.* 9, 1718. PAUL D. FOOTE.

Some characteristics of cathode ray tubes. J. P. MINTON. *Gen. Elec. Rev.* 18, 636(1915).—The vacuum characteristics and cathode electrostatic effects of cathode ray tubes are discussed. Vacuum changes are not due to large ends of the tubes in which screens were placed because "softening" effects were observed for small test tubes. Expts. also show that water vapor is not responsible for this "softening" effect. A short review of the causes of cathode electrostatic effects is given. W. E. RUDER.

Stassano electric furnace at Redondo. W. M. MCKNIGHT. *J. Elec. Power & Gas* 35, 37(1915).—A description of the first Stassano arc furnace installed in the U. S. It was installed in 1913 to replace the crucible process, has a capacity of 1 ton and has been in continuous operation since installed except for short intervals for re-

lining. Six heats can be run daily. The heat insulation is sufficient to hold the charge molten through a power interruption of 4 hrs. The relining with magnesite 3 times a month requires 2 days and costs \$225.00. This furnace differs from the regular type in that the top has been made removable. The av. arc is 10 in., although at times 18 in. is drawn. The current consumption is 800–2000 amps. per terminal on a 3-phase 150 v. circuit. To keep the balance, a ground connection is tapped through an oil switch and overload release, to the middle point of the Y on the main circuit. There is very little fluctuation, as shown by the graphic chart, from the av. demand of 225 kw.

W. E. RUDER.

New installations of Héroult electric furnaces. ANON. *Iron Age* 96, 337(1915).—The installations of a 3-ton Héroult at Longueuil (Canada), a 15-ton at Canton and a 6-ton at Indiana Harbor are announced.

C. G. F.

Electrolytic cell for preparing alkali amalgams. FRIEDRICH C. G. MÜLLER. Brandenburg. *Z. physik. chem. Unterr.* 28, 148–50(1915).—The bottom of a short, wide-mouthed bottle is cut off and a piece of closely woven canvas drawn over and up the sides about 2 cm. and bound on with a fine Fe wire above the surface of the electrolyte. A large wire is twisted around the neck of the bottle so that 3 arms extend and rest on the edge of a crystg. dish about 8×8 cm., into which 200 cc. of the electrolyte is poured. About 150 g. Hg is put in the bottle. Eight amp. at 12 v. for 10 min. is sufficient to produce considerable quantities of amalgam.

J. H. MOORE.

Notes on the uses of mercury type electrolytic meters. R. BOSSOM. *Electrician* 75, 516(1915).—The great accuracy of this type of meter at all loads, their ability to register very small currents and their extremely low upkeep, make them very desirable instruments to use as "checks" on other meters *in situ*. Some notes are given on methods of testing in quantity. The advantages of this type of meter in dry cell testing and in storage battery charging are discussed.

W. E. RUDER.

Strip electrode. HEINRICH GÖCKEL. Berlin. *Chem. Ztg.* 39, 484(1915).—One side of a strip of sheet Pt is fused into the wall of the vessel, allowing better cooling of the electrode and electrolyte.

J. H. MOORE.

The law of "corona" and spark-over in oil. F. W. PREK, JR. *Gen. Elec. Rev.* 18, 821–7(1915).—It is shown that in general the mechanism of breakdown in gaseous and liquid insulations is very much the same; the general laws which P. has developed for calcg. the breakdown voltages for air apply also to transil oil. Data on the various properties of oil for 60-cycle, high frequency and impulse voltages are given. Curves are given showing the relation of the effective K. V. to the spacing for needles, small (1.1 cm.) and large (12.5 cm.) spheres, and concentric cylinders. The effect of H₂O and temp. are also shown graphically. The permittivity of oil is $2.6 \times$ its sp. gr. The use of barriers, limiting the energy distance, is a great advantage. W. E. RUDER.

Iron losses in transformer plate. A. PRESS. *Electrician* 75, 585(1915).—A theoretical paper. C. G. F.

U. S., 1,147,703, July 27. J. W. BROWN. **Electric furnace for manufacture of graphite.** The granular charge is supplied to the upper chamber 13' and passes downwardly through the furnace. Current is supplied through the material as it passes through the restricted portion 12' by electrodes 14 and 14'. Inert gas circulated by the fan 19 cools the product and the conveyer 18 delivers it to the air. Cf. C. A. 9, 1279.

Electric heating element, composed of a metal which melts below the temp. desired in the app., and which in the molten state expands and presses against the walls of the material in which it is embedded, thereby insuring better conduction of heat. For a temp. of 200° , Sn is used, Pb for 300° , Zn for 400° , and Al for 600° .

Ger., 283,613, Nov. 29, 1912. DEUTSCHE GASGLÜHLICHT-AKT.-GES. (AUER-GESELLSCHAFT.) Electric gas or vapor lamp, filled with rare gas and provided with an auxiliary electrode.

Ger., 283,765, Sept. 15, 1910. THE NITROGEN CO. Obtaining alkali or alkaline earth metals by the electrolysis of a fused electrolyte, employing an anode consisting of an alloy of the alkali or alk. earth with a heavy metal. A molten cyanide or

cyanamide compd. of the alkali or alkaline earth metal sought is employed as electrolyte. Pb has proved desirable as the alloy metal of the anode. In one cell, the alkali and alk. earth compds. are electrolyzed with the alloy metal as cathode, and in a 2nd cell the resulting alkali or alk. earth heavy metal alloy acts as the anode. The electrolytes employed in the 2nd process heretofore, such as molten NaCl, NaBr, or NaI, or molten mixts. of KOH and NaOH, did not give economical results. Better results were obtained by the use of electrolytes composed of molten cyanide or cyanamide compds. of the alkali or alk. earth metals, inasmuch as the CN compds. do not combine with the Pb of the anode, even at the high temps. (red heat) necessary for the formation of the anode alloy in the primary cell. By maintaining a temp. of 700-800° the production of the alkali or alk. earth metal in the 2nd cell can be rendered continuous, without the necessity of constantly regulating the temp., noting the current d., or exercising care as to the comp. of the alloy. The alkali or alk. earth heavy metal alloy, which serves in the 1st cell as cathode and in the 2nd cell as anode, may be allowed to circulate continuously between both cells, thereby equalizing the temp. and agitating the electrolyte.

Ger., 283,886, Apr. 15, 1913. ELEKTRO-OSMOSE-AKT.-GES. (GRAF SCHWERIN-GES.). Mfg. soluble chemically pure silicic acid by subjecting to the action of the elec. current, alkali silicate solns. in the anode chamber of a cell provided with diaphragms, of such potential as to prevent simultaneous diffusion of alkali and silicic acid. A 5-10% alkali silicate soln. is poured into a diaphragm cell or into the anode side of a diaphragm app. Perforated electrodes, resting on the wall of the diaphragm, are used preferably. This diaphragm is placed in a vessel filled with pure H₂O, a wire gauze, mounted on the outer wall of the cell, serving as the cathode. The mounting of the electrodes on the wall of the diaphragm prevents the sepn. of amorphous silicic acid. Pt wire gauze is used for the anodes in the production of silicic acid for medicinal purposes, while the Pb-Sb anode, according to 251,098 (C. A. 7, 29), is used in mfg. a tech. product. A brass wire gauze can be used to advantage for the cathode. When the current is passed, the alkali passes through the diaphragm into the cathode chamber, while sol. silicic acid remains in the anode chamber. By choice of a suitable diaphragm the silicic acid is prevented from entering the anode chamber, which is possible on account of its amphoteric character in the colloid-chem. sense. Therefore, such a potential is given to the diaphragm that only the alkali passes through the diaphragm while the silicic acid remains in the anode chamber. Preferably a diaphragm is made of a mixt. of carborundum and corundum. At first a low tension can be employed, while finally, in order to eliminate the last traces of alkali, the tension is raised to 60-70 v. In order to remove the last traces of mineral acids and CO₂ from the silicic acid, an anode purification is allowed to follow the cathode treatment. For this purpose, the silicic acid is charged into a vessel serving as cathode, while the anode is surrounded with a diaphragm of parchment paper. Upon passage of the current the acid residues pass through the diaphragm from the cathode to the anode, while the sol. silicic acid does not change. In proportion to the passage of the acid residues, the v. is increased, in order that the last traces of acid may be rapidly eliminated. The silicic acid product is chem. pure and stable when properly preserved; it also possesses a very low mol. wt.

5. PHOTOGRAPHY.

LOUIS DERR.

New researches on metallic clouds. IV. Effect of light on solid silver chloride and silver bromide. A contribution to the theory of the latent photographic image. RICHARD LORENZ AND K. HIRGE. Frankfurt a/M. *Z. anorg. allgem. Chem.* 92, 27-

34(1915).—To obtain evidence as to the relation between metallic clouds (cf. *C. A.* 9, 1565) and the latent photographic image, optically clean, clear AgBr and AgCl crystals were prepd. as before and the changes caused by illumination observed. On exposure to light, a very fine cloud first develops in the crystal; this grows until the particles become visible in the ultramicroscope. When a prepn. is exposed to light until the fine cloud forms, then heated in the dark at 350°, some of the particles grow at the cost of the surrounding cloud; blank expts. showed no effect. It is concluded that the latent image produced by exposure of a photographic plate to light is primarily a metallic cloud, similar to those previously described. GEORGE W. MOREY.

6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

The double salt of sodium and potassium sulfates. KICHIRO OKADA. *Mem. Coll. Sci. Kyoto* 1, 95-103(1914); *J. Chem. Soc.* 108, II, 344.—The equil. relationships in the system $\text{Na}_2\text{SO}_4\text{--K}_2\text{SO}_4\text{--H}_2\text{O}$ have been investigated at 15°, 25°, 40°, 50°, 60°, 70° and 80°. Mixts. of Na and K sulfates in varying proportions were shaken with an equal wt. of H_2O for about 24 hrs., and the compn. of the satd. soln. and of the residue detd. by the tartrate method (cf. *C. A.* 9, 2492). From the results, the conclusion is drawn that Na and K sulfates form a double salt of the formula $\text{K}_2\text{Na}(\text{SO}_4)_2$. This double salt forms solid solns. with Na_2SO_4 , but not with K_2SO_4 . The limits of existence of the solid solns. become more widely sepd. as the temp. rises from 15 to 60°, but approach one another between 60 and 80°. Up to 60° O.'s data are in accord with those obtained by Nacken (*C. A.* 5, 17), but this observer assumes that the solid soln. field widens with rise of temp. up to 180°. E. J. C.

Oxidizing properties of sulfur dioxide. J. A. SMYTHE AND W. WARDLAW. *Proc. Durham Phil. Soc.* 5, 187-201(1913-14); *J. Chem. Soc.* 108, II, 335.—Hitherto known reactions in which SO_2 behaves as an oxidizing agent are summarized. The oxidizing action of SO_2 on the lower chlorides of Sn, Ti, Hg and Fe has been investigated. SnCl_2 and TiCl_3 were oxidized in warm, strongly acid soln. to SnCl_4 and TiCl_4 , the SO_2 being reduced to H_2S . In solns. not too strongly acid, the corresponding sulfides were accordingly pptd.; otherwise S was formed: $3\text{SO}_2 + 12\text{HCl} + 6\text{SnCl}_2 = 6\text{SnCl}_4 + 6\text{H}_2\text{O} + 3\text{S}$ and $3\text{SO}_2 + 12\text{HCl} + 12\text{TiCl}_3 = 12\text{TiCl}_4 + 6\text{H}_2\text{O} + 3\text{S}$. In concd. HCl, HgCl_2 was slowly but completely oxidized, with the deposition of S; no H_2S was formed. In strong acid soln., only about 7% FeCl_2 was oxidized on the average, and increase in the total conc. of the Fe lessened the relative amt. of Fe^{++} salt. The SO_2 was reduced to S. The reaction is not a balanced one, but appears to be brought to a standstill by direct inhibition by the FeCl_3 . When more than 14% of the total Fe was in the Fe^{++} state, no S was deposited on leading in SO_2 , and no oxidation took place at all. It is suggested that the oxidizing action of SO_2 in the above cases, which is only manifested in presence of conc. HCl, may be due directly to the intermediate formation of SOCl_2 . E. J. C.

Complex compounds of platinum with tellurium ethers. É. FRITZMAN. *J. Russ. Phys. Chem. Soc.* 47, 588-90(1915).—Te ethers, like the S ethers (Chugaev, "Chem. Constitution of Complex Compds.," 1910, St. Petersburg), are capable of forming complexes with PtCl_2 . To prep. *platinumdichlorodibenzyl telluride*, $\text{PtCl}_2 \cdot 2(\text{PhCH}_2)_2\text{Te}$ or, in Werner's system, $\text{Pt}_2(\text{C}_7\text{H}_7)_4 \cdot \text{Te} \cdot \text{Cl}_2$, either of the following methods may be used: alc. $(\text{PhCH}_2)_2\text{Te}$ (a) is mixed with aq. K_2PtCl_4 , or to (a) in abs. alc. is added $(\text{Pr}_3\text{N})_2\text{PtCl}_4$. The substance is a greenish orange, microcryst. powder (from CHCl_3), beginning to darken and decomp. 115-20°, but not m. even at 200°, stable when dry, but quickly

decomp. in soln. with formation of Pt, Te and $(\text{PhCH}_2)_2$, readily sol. in CHCl_3 or CHBr_3 , difficultly in alc., and insol. in Et_2O . Its mol. wt. was detd. cryoscopically in CHBr_3 . Similar compds. of other Te ethers are under exam. H. M. GORDIN.

Calcination of magnesium ammonium phosphate and the factors which cause it to turn black. JOSÉ GIRAL PEREIRA. Salamanca. *Anales soc. españ. fis. quim.* 12, 109-12 (1914).— Mg NH_4 phosphate was obtained by the warm pptn. of NH_4 phosphate with an acid magnesia mixt. (Schmidt procedure); the primary reagents were carefully tested for purity (especially regarding the absence of pyridine in the NH_4OH). Filtration was effected in a Gooch crucible with calcined asbestos and excess of NH_4OH was removed by washing with distd. H_2O ; the use of filter paper or any other organic material was avoided. The Mg NH_4 phosphate was then subjected to various tests; in some cases the ppt. remained perfectly white, while in other cases it acquired a grayish or blackish tint. The latter ppts. gave positive tests (coloration of flame, action of acids, blackening of AgNO_3 , etc.) for phosphides, while the white ppts. gave negative tests. The results appeared to justify the following conclusions: (1) blackening is caused by any one of a number of various organic materials (pyridine, filter paper, etc.); (2) blackening of Mg pyrophosphate is, in many cases, independent of the manner in which calcination of Mg NH_4 phosphate is effected; (3) production of phosphides appears to be due to the reduction of Mg pyrophosphate by the C of organic material which is present; (4) a gradual increase in temp. during calcination is not necessary in order to obtain a white residue in case organic substances are absent; (5) absence of organic material always results in white residues without a trace of coloration. H. S. PAINÉ.

7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

Standardized colored fluids. H. V. ARNY AND C. H. RING. *J. Frank. Inst.* 180, 199-213 (1915).—In continuance of previous work (*C. A.* 8, 2540), the authors prepared 0.02 *N* solns. of CoCl_2 (red), $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$ (yellow), and CuSO_4 (blue). When mixed in various proportions they produce all hues except a few delicate pinks and violets, which are reproduced by 0.001 KMnO_4 and $\text{K}_2\text{Cr}_2\text{O}_7$ solns. The above colors give better results than those previously used. These solns. may be used to prepare scientific color standards. H. C. BERMAN.

A new method for the determination of alkalinity and acidity. I. TRAUBE. *Ber.* 48, 947-9 (1915); see *C. A.* 9, 213. E. W. BOUGHTON.

Determining weight of deposit. L. C. WILSON. *Metal Ind.* 13, 152-4, 277-8 (1915); cf. *C. A.* 9, 756.—Cu coatings are seldom of uniform wt. over the plated part. To det. areas of light and heavy deposit, cover the article completely with beeswax, remove this from the areas in question and immerse the article in dil. HNO_3 (1:3). Det. Cu in the soln. by any of the common methods. H. L. OLIN.

Estimation of sodium and potassium in a mixture of their salts. KICHIRO OKADA. *Mem. Coll. Sci. Kyoto* 1, 89-93 (1914); *J. Chem. Soc.* 108, II, 373.—The method depends on the slight solubility of K H tartrate and on the fact that when a definite quantity of a mixt. of Na and K salts is added to a fixed quantity of Na H tartrate in soln., the conc. of tartrate remaining in the soln. at const. vol. and temp. is a function of the % of K salt in the mixt. Shake the soln. for at least 5 hrs. at 25° , and evap. a fixed vol. of the clear soln. to dryness; heat the residue to redness. Then add a definite vol. of standard HCl and titrate the excess of acid by means of a standard NaOH . Det. the vol. of standard HCl neutralized by the residue by means of expts. with mixts.

of varying comp. Plot this vol. against the % molar compn. of the mixt., and utilize the curve thus obtained in the evaluation of unknown mixts. E. J. C.

Volumetric determination of aluminium. I. P. OSIPOV. *J. Russ. Phys. Chem. Soc.* 47, 613-5(1915).—A comparison of the results in the detn. of Al by Stock's method (*Compt. rend.* 130, 175) and by its modifications proposed by Moody (*Z. anorg. Chem.* 46, 424), Ivanov (*C. A.* 8, 3765) and Kovsharova (following abstr.) showed that K.'s method is the most convenient and most exact. H. M. GORDIN.

Application of Stock's reaction to the volumetric determination of aluminium. T. V. KOVSHAROVA. *J. Russ. Phys. Chem. Soc.* 47, 616-24(1915).—Al may be detd. volumetrically by the following modification of Stock's method (cf. preceding abstr.): To the mixt. of ingredients given in S.'s equation add an excess of 0.1 *N* $\text{Na}_2\text{S}_2\text{O}_8$, and after warming for a short time, titrate the excess of the latter with 0.1 *N* I. As the conditions of the reaction were found greatly to affect the exactness of the method, a very large number of expts. were made in order to det. the influence of each of the factors. The results are given in several tables, but as the work had to be discontinued, no definite conclusions were reached. Tentatively the following conditions are set up as conducive to obtaining good results: The excess of $\text{Na}_2\text{S}_2\text{O}_8$ must not be great, the mixt. must be as neutral as possible, and the heating should not last more than 20-30 min. H. M. GORDIN.

Rapid electrolytic methods for the determination of copper. M. NAKAO. *J. Pharm. Soc. Japan* 1915, No. 400, 666.—From comparative tests of rapid electrolytic methods for Cu, N. concludes that for the pptn. of 0.25 g. Cu in 125 cc. HNO_3 - H_2SO_4 soln. within 10 min. the following conditions should be observed: (1) the use of a gauze electrode according to A. Fischer; (2) speed, 800 r. p. m.; (3) temp. 50°; (4) acid content of soln. 10 cc. concd. H_2SO_4 , 1 cc. dil. HNO_3 ; (5) the addition of 10 g. $(\text{NH}_4)_2\text{SO}_4$ and 0.3 g. acetamide. The high acid content shortens the process by maintaining a high cond. while the salt and acetamide destroy any HNO_2 formed and insure an oxide-free ppt. H. L. OLIN.

Determination of arsenic. HERMAN PALME. *Svensk Farm. Tidskrift* 19, 333-5 (1915).—The official method for the detn. of As in cases of poisoning, based on the reduction of the As with SO_2 and titration with 0.002 *N* I soln., gives low results when the As present exceeds 0.5 mg. The various steps in the method were carefully examd. and the only discrepancy noted was in the time element of contact of the SO_2 with the sample. Instead of letting the HCl distillate to which SO_2 has been added stand 2 hrs., P. recommends that it be set aside until the next day before the SO_2 is removed by evapn. and the arsenious acid titrated. In some cases it is advisable to add more SO_2 after standing some time. P. also suggests the use of 0.01 *N* I for samples high in As. Tables show variations of 0.01 to 0.38 mg. from the theoretical amts. in detns. with 2 hrs. contact with the reducing agent, and in detns. in which the mixt. stood 12 hrs. the differences were 0 to 0.06 mg. The total amts. in the samples used ranged from 3 mg. to 14 mg. As. A. R. ROSE.

The Fresenius-Babo soda-potassium cyanide method for the determination of arsenic. PETER KLASON. *Svensk Kem. Tidskrift* 27, 101-11(1915).—A brief critical review of the literature on the detn. of As and a careful lab. exam. of the Na_2CO_3 -KCN method. The tests were made on the oxides and sulfides derived from a pure prepn. of H_3AsO_4 . The fusion mixt. used was 0.3 g. Na_2CO_3 and 0.1 g. KCN. It was placed in the 3.5 cc. bulb of the As tube. The tube was provided with an asbestos plug and to prevent "back sublimation" a glass rod was inserted in the other end. The CO_2 current was passed through at a rate of 2 bubbles per sec. Expts. showed that this gas need not be dried. The As capillary tube must be clean, especially free from fatty

matter. The bulbud tube rested on the Argand burner and was carefully manipulated in the flame. The completion of the reduction was manifested by the clearness of the melt. With a single burner about 98% of the As is recovered; by applying the flame of a micro-burner to the capillary, a second mirror is formed and there is complete recovery of the As. The As mirror was weighed on a micro-balance after drying at 100° for 10 min. A drop of water is passed through the capillary to dissolve part of the melt carried over mechanically. The tare wt. of the capillary is obtained by driving off the As mirror with the least necessary free flame. Some mirrors were converted into arsenic acid and titrated with 0.001 *N* Ba(OH)₂ (phenolphthalein indicator). This titration is sensitive to better than 0.1 cc. of the Ba(OH)₂ soln. In titration, the As equiv. is 37.9. The forms of As used were As₂O₃, As₂O₅, As₂S₃, As₂S₅; the amts., 0.0375 to 1.125 g. The max. error in the total amt. of As in the sample used was 4%; in most cases the loss of As did not exceed 0.005 mg. The reactions involved are discussed. K. does not consider that the KCN enters into the reduction reaction when the As is under 3 mg. to 200 mg. melt. In these amts. there is no KCNS formed in the reduction of As₂S₃. The KCN is introduced chiefly to facilitate fusion. The sensitiveness of the method as a test is shown by mirrors obtained after dilns. of the H₂AsO₄. Two cc. 0.0001 *N* soln. gave a transparent mirror 6 mm. long; a trace of a mirror was noted from 1 cc. 0.000001 *N* of the H₂AsO₄ soln.

A. R. ROSE.

H. L. OLIN.

The determination of selenium in organic compounds. A. MICHAELIS. *Ber.* 48, 873-4(1915).—A statement that M.'s method is reliable and simple as has been confirmed by Bauer. Cf. *C. A.* 9, 2205.

E. W. BOUGHTON.

The detection of methane. II. O. HAUSER AND H. HERZFELD. *Ber.* 48, 895-6 (1915).—The method is based on the fact that CH₄ and ozone react to form CH₃O (cf. *C. A.* 7, 1152). The ozone is prepared by the electrolysis of dil. H₂SO₄ using Pt electrodes. The one serving as anode is sealed through the wall of the tube in such a manner that half of it extends on the inside and half on the outside of the tube. If the tube is cooled with ice water during electrolysis, a sufficiently low temp. is reached to prevent the decompn. of the ozone. The gas mixt. to be tested is conducted into a side branch of the anode tube where it comes in contact with the ozone. The resulting CH₃O is absorbed by moist glass wool and is detected by morphine-H₂SO₄. 1.9% of CH₄ in the air may be easily detected.

E. W. BOUGHTON.

A modified reduction method for the volumetric determination of nitro compounds. A. J. BERRY AND C. K. COLWELL. *Chem. News* 112, 1-2(1915).—To the soln. of the nitro compd. add an excess of standard SnCl₂ soln. with HCl and a measured quantity of strong KBr soln. Pass in a current of CO₂ and boil for 15 min. RNO₂ is reduced to RNH₂, while Sn⁺⁺ becomes Sn⁺⁺⁺. Titrate the excess of Sn⁺⁺ with a strongly acid standard Cu⁺⁺ soln. to which is added KBr. This brown-violet soln. becomes orange-yellow on reduction and no other indicator is necessary. The SnCl₂ must be standardized with the Cu soln. before each detn. Accuracy, 1-2%. H. L. OLIN.

Notes on the galactan determination. W. H. DORE. *J. Ind. Eng. Chem.* 7, 721-2(1915); cf. Miyake, *C. A.* 6, 2958.—Criticism of the official method (Bur. of Chemistry, *Bull.* 107).

EDGAR T. WHERRY.

A preliminary check-list of Philippine minerals. WARREN D. SMITH, F. T. EDDINGFIELD AND PAUL R. FANNING. Div. Mines, Bur. Sci., Manila. *Philippine J. Sci.* 10 (A), 81-96(1915).—The 113 mineral species and varieties which have been identified with certainty from the Philippines are listed alphabetically, with notes on their geologic relations, localities, and economic value. E. T. W.

The constitution of sphalerite, wurtzite, and hauerite. A. BRUTELL AND M. MATZKE. Breslau. *Centr. Min. Geol.* 1915, 263-72.—A continuation of the studies of B., C. A. 5, 2795, 3667; 6, 466, 2051; and of Arbeiter, C. A. 8, 646. The disulfides and diarsenides studied appeared to owe their dimorphism to difference in chem. constitution, so a similar investigation has been extended to the monosulfides of Zn, sphalerite and wurtzite. To test the conclusions of Weber (C. A. 2, 1253) that the former of these contains too much S, the latter too little for the formula ZnS , very accurate analyses were made of 2 samples of each and the 1:1 ratio found to hold exactly. Expts. with Ag foil (cf. B., C. A. 8, 1074) were also made with these and other specimens, and free S (or S held in solid soln.) found to be absent. Weber's views could thus not be confirmed. The detailed results of studies of the 2 minerals are to appear in a dissertation by Matzke; the main conclusions are here presented. When treated with dil. H_2O_2 soln. both minerals yield Zn and S to the soln. in identical ratio, exactly 1:1. As this result is not dependable, since it is controlled by the fact that the H_2SO_4 formed dissolves an equivalent amt. of ZnO, the expt. was repeated with H_2O_2 soln. made alk. with Na_2CO_3 . Sphalerite then yielded Zn:S in the ratio 1.18-1.63:1, while in wurtzite it was much nearer 1:1. In the former the variation was found to be proportional to the diln. of the H_2O_2 soln.; in the latter the ratio was independent of this factor. The limiting ratio in the case of ZnS is 2:1; it follows that, on oxidation, half of the S of sphalerite seps. as free S and the other half oxidizes to H_2SO_4 . With wurtzite the results varied slightly, because of the impurities present, so pure artificial material was prepared, and it gave results showing conclusively that in this mineral all the S goes to H_2SO_4 . The presence of free S in the oxidized sphalerite was proved by heating in a vacuum, while wurtzite under like conditions gave no S. These behaviors are in ac-

cord with the following structure for wurtzite: $Zn \begin{array}{c} \diagup S \diagdown \\ \diagdown S \diagup \end{array} Zn$. Sphalerite must have at

least the 4-fold formula Zn_4S_4 ; there are then different possibilities for its constitution, but the data at hand are insufficient to decide between them. It is noteworthy that the röntgenograms of sphalerite which have been made by Bragg and others give no aid in this direction, as they indicate no chem. difference in the S atoms. A crystal of hauerite, MnS_2 , shown by analysis to be pure, was tested in the same way, although

here the air was an adequate oxidizing agent. The results showed that in the oxidation of this mineral no S was oxidized to H_2SO_4 . In pyrite, on the other hand, $\frac{1}{4}$ of the S is thus oxidized, so it follows that hauerite does not belong to the pyrite group. It is possible that in hauerite the Mn is tetravalent, but since both S atoms behave alike no definite indication as to its constitution can be obtained. E. T. W.

The modifications of witherite at high temperatures. I. SAMOILOV. Moscow. *Centr. Min. Geol.* 1915, 161-3; H. E. BOEKE. Frankfurt. *Ibid* 272.—S. announces the discovery of a new modification of witherite, which he names β -witherite; it forms on heating at 970° , and disappears again on cooling at 940° . B. points out that he had previously observed the same modification (C. A. 7, 3946). E. T. W.

The law of admixture of the alkali-free augites. G. TSCHERMAK. *Centr. Min. Geol.* 1915, 225-32.—A reply to Boeke (C. A. 9, 2045). The difference of opinion which has arisen is largely a question of terminology and definition. The relations shown by some of the best analyses of augite are discussed in detail, and shown to substantiate T.'s former conclusions that the augites are isomorphous mixtures. Four components have been used for convenience in discussion, but 3 are likely to prove sufficient, namely CaSiO_3 , MgSiO_3 , and Al_2O_3 . E. T. W.

Vesuvianite and hastingsite from the nepheline-syenite from Almunge. PERCY QUENSSL. Stockholm. *Centr. Min. Geol.* 1915, 201-8.—Vesuvianite, which is usually a contact-metamorphic mineral, has been found to be an abundant accessory constituent of the nepheline-syenite rock from Almunge, near Upsala (C. A. 8, 2863). The mineral forms prismatic crystals up to 2 cm. long, with $\omega = 1.7311$, $\epsilon = 1.7269$ and the comp. SiO_2 36.16, TiO_2 2.49, Al_2O_3 17.59, Fe_2O_3 3.91, FeO 1.80, MnO 0.34, MgO 0.81, CaO 33.67, K_2O 0.13, Na_2O 0.86, H_2O 2.10, sum 99.86%. This is somewhat abnormal in that $\text{RO}:\text{R}_2\text{O}_3 = 3.3:1$ instead of $4:1$, but this is sufficiently explained by the unusual mode of occurrence. The presence of this mineral is best explained on the basis of assimilation, by the magma, of calcareous rocks. The amphibole of the rock from Almunge proves to be optically similar to hastingsite, with which its comp. also agrees. No simple or strict definition of the hastingsite group has heretofore been given; the most characteristic optical features are the small to minute axial angle, the variable position of the optic axes, the very low birefringence, strong dispersion and blue or blue-green absorption colors; the chem. features are low Al_2O_3 (about 10%); about the same amt. Fe_2O_3 ; 20-5% FeO [in original the last 2 oxides are interchanged by mistake.—ABSTR.]; about 10% CaO ; and low alkali content. Amphiboles belonging to this group have been given various names, as hudsonite and hornblende; apparently a single series is represented, extending from barkevikite through alkali-amphiboles to typical hastingsite. E. T. W.

Has the existence of crystallized hydrous silicates with dissolved or absorbed water been proved? A. BEUTELL AND K. BLASCHKE. Breslau. *Centr. Min. Geol.* 1915, 195-200.—Having proved that the H_2O in stilbite is chemically united (C. A. 9, 2046), B. and B. have now critically considered all previous observations on hydration and dehydration of hydrous silicates which have been regarded as indicating that their H_2O is either dissolved or absorbed. They find that in no case has the effect of cohesion, in holding the H_2O of higher hydrates until lower ones begin to decompose and so rendering the curves smooth, been avoided, so that the answer to the captioned question is negative. E. T. W.

The systematic classification of ore deposits. R. BECK. Freiberg. *Centr. Min. Geol.* 1915, 272-7.—B. points out that Sachs (C. A. 9, 2046) has misquoted his classification of ore-deposits, and as others have also not comprehended it fully, he restates the principles on which it is based. The revised classification is as follows:

Arranged according to phases of historical development.		Designated according to relative age of ore and associated rock.
I. Magmatic segregations		Syngenetic Group A
II. Contact-metamorphic ore-deposits		Epigenetic Group A
III. Lodes (Gänge)	} { Morphologic facies of a single genetic group	Epigenetic Group B
IV. Beds (Lager)		
V. Shoots (Stöcke)		
VI. Gossan-formations		Epigenetic Group C
VII. Sedimentary ore-deposits		Syngenetic Group B
VIII. Gravel deposits (Seifen)		Syngenetic Group C

Origin of "sandstone" ore-deposits. CHESTER T. KENNAN. *Mining Eng. World* 43, 213-5(1915).—A summary of our knowledge as to the manner of introduction and pptn. of ores in porous rocks such as sandstone and conglomerate. Many examples are cited.

E. T. W.

The copper deposits of San Cristobal, Santo Domingo. THOMAS F. DONNELLY. *Bull. Am. Inst. Mining Eng.* 1915, 1759-68.—The region consists of Cretaceous limestone in contact with post-Cretaceous igneous rocks, principally basalt and basic tuffs cut by trachyte dikes. The 2 promising sources of ore are (1) the deposits that should occur at the contact of the igneous rocks with the limestone, which constitutes a zone 4,000 ft. in length; and (2) the fissure veins, filled with white quartz carrying as its principal Cu mineral bornite, with minor quantities of azurite and malachite. Labor conditions in the region are favorable.

H. L. OLIN.

Ore bodies of the Mesabi range. J. F. WOLFF. Duluth, Minn. *Eng. Mining J.* 100, 89-94, 135-9, 178-85, 219-24(1915).—This paper comprizes "a practical and untechnical summary of what is known as to the physical structure of these ore bodies. . . and many newly discovered facts. . ." This is treated under the headings: general geology and structure, the ore bodies as developed, their exploration and development, and the details of the geology and origin of the ores. In the last part a good discussion of the mode of conc. of the Fe ores is given.

E. T. W.

New studies on the black sands of Madagascar and the platiniferous quartzites of Westphalia. LOUIS DUPARC. Geneva. *Arch. sci. phys. nat.* 38, 401-9(1914); continuation of C. A. 8, 1725.—Specimens of these materials were studied spectrographically, both in their original form and after fusion with litharge. Only the faintest traces of Pt lines were observed, and these were due to a trace of Pt in the litharge. There is certainly no commercial amt. of Pt in either the black sands or the quartzites.

J. H. BOWER.

Potash deposits in Chile. SEVERO SALCEDO. New York. *Eng. Mining J.* 100, 218(1915).—The salts in lake beds in Tarapaca province, Chile, are shown by analysis to contain up to 14.15% KCl, with 51% NaCl and 28% Na₂SO₄, but with only traces of other substances, the absence of Mg, which is so prominent in the Stassfurt salts, being noteworthy. A very large deposit is believed to exist, and local conditions are favorable for its becoming of commercial importance.

E. T. W.

Magnesite deposits in British Columbia. R. E. MANSFIELD. *Commerce Repts.* 177, 517(1915).—Large new deposits have been found along the shore of Lake Atlin.

E. H.

Phosphate rock in Johnson County, Tennessee. JOEL H. WATKINS. Washington, D. C. *Mining Eng. World* 43, 217-8(1915).—Rock averaging 75.21% Ca₃(PO₄)₂ has been discovered interbedded in a shale formation. It has perhaps formed by replacement of brecciated limestone beds by ascending phosphatic solns.

E. T. W.

The occurrences of petroleum in eastern Mexico as contrasted with those in Texas and Louisiana. E. T. DUMBLE. *Bull. Am. Inst. Mining Eng.* 1915, 1623-38.—Mexican deposits so far as developed originated in a single horizon in a field which has been subjected to strong orogenic forces, while those of Texas and Louisiana are found at many other horizons, ranging from the Pennsylvanian to the Pliocene, in areas in which there is little evidence of orogenic action. H. L. OLIN.

Composition of the solid fraction of the naphtha paraffins as a criterion of its geologic age. M. A. RAKUZIN. *J. Russ. Phys. Chem. Soc.* 47, 641-2(1915).—In a former article (*C. A.* 9, 2148) it was shown that floridin(?), kaolin and other minerals are capable of adsorbing all of the lower paraffins from naphtha. Hence the relative age of a given sample of it and the relative depth in the earth where it was originally formed may be judged by the amt. of such paraffins it contains, the deeper the sedimentary strata where it originated, *i. e.*, the older it is, the more of these paraffins being adsorbed during its filtration through minerals to the surface. H. M. GORDIN.

Causes of formation of natural naphtha. A. E. CHICHIBABIN. *J. Russ. Phys. Chem. Soc.* 47, 714-6(1915).—The catalytic influence of metallic oxides and certain salts on the formation of S- and N-containing substances (*cf. C. A.* 9, 2512) and on the condensation of lower to higher hydrocarbons observed by Sabatier and by Ipat'ev lends support to the hypothesis of the mineral origin of naphtha, there being an abundance of such catalyzers in the bowels of the earth. As to the optical activity of natural naphtha, it speaks neither for nor against this hypothesis, until its exact causes are learned. To assume that this activity is due to living forces is for the present unwarranted. H. M. GORDIN.

Notes on the analysis of "iron-stone." H. B. VICKERY. Dalhousie Univ., Halifax, N. S. *Proc. Trans. Nova Scotian Inst. Sci.* 13, No. 3, 209-15(1912-13).—A number of analyses have been made of this stone, which contains SiO_2 , Al_2O_3 , FeO , Fe_2O_3 , MgO , S, volatile matter and H_2O . The results obtained show that considerable variation in comp. may occur. The low proportion of volatile matter and S, and the high SiO_2 content are significant of the effect of the granite intrusion upon the slate in its immediate vicinity. Microscopic exam. revealed the presence of feldspar, but in such small amt. that no est. was made of the alkalies. H. J. CREIGHTON.

Systematic classification of concretions. RAPHAEL E. LIESEGANG. Frankfurt. *Centr. Min. Geol.* 1915, 257-63.—Concretions, like crystals, form by a segregation of originally scattered material. The primary division of concretions into types may be based on whether this original material was previously present as such or has been formed by chem. reaction. Even this sepn. is not sharp, for on the one hand a new substance may be formed, even though the original one traveled in supersatd. soln., and on the other hand a substance, as for instance CaCO_3 , is dissolved by CO_2 and transported as a bicarbonate, yet on pptg. forms the original carbonate again. In spite of the manifest incompleteness of any scheme of classification, several are proposed, as follows: I (A) origin from material already present; (B) origin by formation of new chem. compd. I (A) can be subdivided according to the transportation of the substance: (a) in soln., (b) in fused condition, and (c) in gaseous form, and a still further division may be based on whether the substance was (a) wholly and (B) only temporarily in the form (a), (b), or (c). Thus I (A a B) would indicate that the concretion formed by the growth of large particles at the expense of small ones through an intermediate soln. It must be noted that true solns. and not colloidal solns. are considered, since the latter are non-diffusible. I (B) can be subdivided like I (A) in so far as only one substance is concerned, but if 2 or more react, an additional class (d), one component solid, must be introduced, and one small letter should be used for each component. Subdivision II is based on the different causes of change to the solid condition. If the sub-

stance was already formed [I (A)], then the subdivision is the same as for crystn., namely: (A) decrease of solvent, (a) by evapn., (b) by addition of a readily sol. but chem. inert substance; (B), cooling; and (C), increase (or in certain cases decrease) of pressure; (D), by temp. increase, may be added, though it is of limited application; and (E), by chem. change, covers the cases of I (B). Subdivision III comprizes the reasons for the localization of the deposit. In most classifications divergences are emphasized; here, however, similarities are considered. When many nuclei are present induration or deposition in large masses is likely to occur, but it is otherwise when: (A) nuclei are present but are few in number; these may be (a) solid particles of the same substance which have sepd., (b) antecedent nuclei (*Vorkeime*), or substances which can react to ppt. nuclei, (c) nuclei which cause the pptn. by physical means; (B) no nuclei are present, when the pptg. substance and the medium in which the concretion forms are of great influence on the nature of the resulting deposit; (C) a chem. decomp. with a pre-existing solid mass takes place, comprizing (a) penetration-pseudomorphs after crystals and the remains of organisms, and (b) formation of crusts around these; the cases under (a) are, indeed, not usually classed as concretions (original erroneously has "pseudomorphs" here.—ABSTR.), but they must be included in a genetic classification. IV. The subdivision according to the direction of growth, which has heretofore played an important role. Todd distinguished concretions and incrustations, Johnsen concretions and secretions, Dana centrifugal and centripetal concretions. In general, where a nucleus acts, growth must be from the nucleus outward and therefore centrifugal. But later changes such as weathering, recrystn., etc., may work in the opposite direction and obscure the original relation. The extent to which diln. can det. the direction of concretionary growth was shown by the following expts.: a cube of NaCl was immersed in conc. AgNO_3 soln.; AgCl replaced the surface layers, and as the AgNO_3 penetrated deeper and deeper, the whole crystal was gradually changed, by centripetal growth, into a concretion-pseudomorph. On performing a similar expt. with dil. AgNO_3 soln. AgCl first formed over the surface of the crystal, and as NaCl diffused outward, this crust increased by centrifugal growth. In nature certain replacing substances, especially Fe hydroxides, seem especially likely to follow the latter process, although when these replace pyrite either type of concretion may develop. Under IV are therefore distinguished (A) endogenous pptns., (B) exogenous pptns., and (C) a combination of (A) and (B). Other possible methods of classification could be worked out, such as a purely chem. one, in which the usual mineralogical plan would be followed, one based on the crystallinity or amorphous character of the deposit, or one based on the medium in which the concretion forms. There may be difficulty in bringing special cases into the proper subdivisions, but this system of classification will at least make it possible to express, by means of a few symbols, the explanation which it is desired to apply to a given occurrence. (Abstracted at length not because the particular letters used are worth anything, but because it is a very illuminating and inspiring treatment of an important but much abused subject.—ABSTR.] E. T. W.

Regular intergrowths in barium bromate crystals (AMINOFF) 2. Optical rotatory power in lithium sulfate monohydrate (JOHNSON) 2.

9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

Pierre Martin and modern siderurgy. E. DEMENGE. *Rev. gen. sci.* 26, 427-30 (1915).

E. J. C.

Applications of oxygen in metallurgy. J. E. JOHNSON, JR. *Bull. Mining Met. Soc. America* 8, No. 2; *Met. Chem. Eng.* 13, 483-4(1915); cf. *C. A.* 9, 194.—Some possible applications of cheap O in the metallurgy of iron are discussed. It is calcd. that with an O and N blast the power required to burn a certain amt. of coke could be reduced by 33%. In the production of ferromanganese the coke consumption can be reduced to one-half with the O blast, and by reducing the vol. and increasing the temp. of the slag the loss of Mn could be cut down; furthermore, the quick drop in the temp. of the gases, due to their small vol., would prevent the volatilization of much of the Mn which in the present practice is being lost in this way. The N discarded from the blast would be valuable. Other applications are discussed.

C. A. NOWAK.

The buying and selling of ores and metallurgical products. CHARLES H. FULTON. *Bur. of Mines, Tech. Paper* 83, 42 pp.(1915).—An outline of underlying principles. A discussion of methods for detg. the various metals in their ores and concentrates as a basis for payment is included.

E. J. C.

Amalgamation tests. W. J. SHARWOOD. *Bull. Am. Inst. Mining Eng.* 1915, 1659-70(1915).—Methods for estg. free or amalgamable ore as distinguished from total ore have not been standardized. S. tabulates with references 26 methods as to app., wt. of ore, size of mesh, wt. of Hg, time, and method of extn. He outlines the following standard test: weigh 100 g. ore into a bottle, add 150 cc. H₂O and 1.5-2 cc. pure Hg from a buret. Clamp the stopper, fold the bottle in a cloth and keep it in the shaker for 2 hrs. Open, and invert it over a 3 in. porcelain dish to allow the clean Hg to run out, adding more H₂O and shaking if necessary. To the Hg in a 250 cc. beaker add 0.5 g. pure Ag foil, add 150 cc. HNO₃ (d. 1.14) previously warmed to 70°, and keep on a hot plate until the Hg has dissolved. Filter the liquid, rinse the residue on to the paper, wash once with 5% HNO₃ soln. and once with H₂O. Sprinkle the paper with test Pb, cover with 15-20 g. Pb, add enough pure Ag to insure parting and 2-3 g. borax glass. Scorify for a few min., pour and cupel. Correct for Au in the Ag and Hg.

H. L. OLIN.

Testing of ores for the cyanide process. WELTON J. CROOK. *Pahasapa Quarterly* 4, Nos. 1 and 2; *Chem. Eng.* 22, 30-2(1915); cf. *C. A.* 9, 2210.—Detailed directions are given for handling the ore and solns. in these tests.

L. W. RIGGS.

Cyanidation of low-grade sulfide ores in Colorado. II. H. C. PARMELER. *Met. Chem. Eng.* 13, 477-9(1915); cf. *C. A.* 9, 2211.—A description of the methods used at the Cariman Mill at Caribou, Boulder County, in working dumps and mines abandoned 30 yrs. ago. The dumps showed an av. Ag content of 7-8 oz. per ton, Au 40-70 cts. per ton. The ore from filled stopes and low-grade veins averaged 15 oz. Ag per ton. The Ag occurs both native and as sulfide. Galena is present in small quantity, and occasionally chalcopyrite occurs. The gang is granitic and very hard. After dry-crushing the ore is re-ground with the addition of mill soln.; CaO is also added to the feed of the first Hardinge (conical) mill; 2 mills are used. Max. size of final product is 12-mesh. The pulp is hydraulically classified and distributed to card tables. The concentrate is shipped to the smelter. The pulp, sand and slime-tailings are sent to the cyanide department. About 35% of the Ag in the ore is recovered in a concentrate containing 100 oz. Ag and 0.50 oz. Au per ton, with 5% of Pb. The tailings from the concg. tables flow to a duplex Dorr classifier, sepg. sand and slime. The sand is charged into leaching vats. A 135 ton vat is under percolation for about 55 hrs. During this period the soln. is strengthened to 2.5 lbs. KCN per ton. When the vat is full, mill soln. at a strength of 1.7 lbs. is turned on for about 100 hrs., then washed with H₂O for 20 to 30 hrs. The pregnant soln. obtained while filling the vat and during the wash with mill soln. all flows to the clarifier and thence to pptn. In treating the slime, de-

cantation and agitation are continuous through a series of one Dorr thickener followed by 3 Dorr agitators and 2 Dorr thickeners. A Portland revolving filter is used to recover cyanide. The slime pulp is thickened to an av. of 50% H_2O . The KCN soln. is raised to 3 lbs. per ton at the first agitator. The agitators are run in series and the transfer of pulp is effected by gravity. The period of agitation is 36-40 hrs. The pregnant soln. from the sand vats and a varying portion of the overflow of first thickener is clarified through filter leaves under vacuum. The clarifier soln. is pumped to a constant-head tank from which the Zn boxes are fed. Soln. is pptd. at the rate of 1.8 tons per ton of ore. The head soln. assays from 1.5 to 1.75 oz. Ag per ton, the tailing soln. 0.02 to 0.05 oz. No Pb acetate is used or other special treatment given. The ppt. is given a light roast in a Case muffle furnace, then fluxed and melted in a Case tilting crucible furnace. The flux found best consists of: Na_2CO_3 5, $Na_2B_4O_7$ 3.5, SiO_2 1.5, MnO_2 1 part by wt. This is used at the rate of 75 lbs. of ppt. The mill soln. contains 1.7 lbs. KCN per ton, with protective alkalinity of 2 lbs. CaO. The consumption of KCN is 1 lb. per ton of ore. CaO consumption is 5 lbs. per ton of ore. The total milling cost is estd. at \$1.72 per ton. The project affords an excellent example of revival in an old mining district, due wholly to improved methods of metallurgy and facilities for economic operation. F. W. SMITHER.

Refining gold by Miller's chlorine process. R. PEARSON. *Bull. Can. Mining Inst.*, July, 1915; *Met. Chem. Eng.* 13, 508(1915).—A description of the process used at the Royal Mint, Ottawa. *Requirements:* a constant supply of Cl gas at a pressure of not less than 5 to 6 lbs. per sq. in.; melting furnaces using either coke or oil for fuel; condensing chambers; suitable pots, tongs, molds, etc. The Cl is delivered from steel cylinders holding 100 lbs. liquid Cl at a pressure of 97 lbs. per sq. in. at 20°. The connections between cylinders and crucibles are Pb pipes, rubber tubing and glass stopcocks. The desired pressure is obtained by connection with a Pb receptacle like a Wolff bottle, the third neck holding a Pb pipe connected with a glass tube which is in turn connected with an enlarged Pb bulb, similar to a large pipet. The Pb receptacle holds sufficient H_2O to give a column of 11 ft. in height (= about 5 lbs. per sq. in. pressure). Should the pressure exceed this amt., the H_2O is forced up into the Pb bulb and the gas escapes outside the building. The cylinders are housed in a cupboard that is ventilated by connection with the furnace flue leading to the condensing chamber and a pipe communicating with the outside air. From 500 to 700 oz. of the metal to be refined are charged into a clay pot and placed in the plumbago crucible in the furnace. Borax is added to form a cover about $\frac{3}{4}$ in. deep. The clay crucible has a clay cover, slotted for the passage of a clay pipe stem, through which the Cl passes to the bottom of the molten mass in the crucible. The Cl is admitted cautiously until it passes with a steady pulsation. Dense fumes of $CuCl_2$ and $PbCl_2$ appear and practically all of the Cl is absorbed. Later $AgCl$ forms and floats above the Au and beneath the borax. The finishing point of the process is judged by the brown stain formed on a cold piece of clay pipe held in the fumes issuing from the pot. The fumes resulting from the chlorination and from the products of combustion are all carried through condensing chambers to a washing tower. When chlorination is complete the pot is withdrawn from the furnace and let cool until the Au sets. Then the borax and $AgCl$ are poured off and sepd. when cold. The $AgCl$ is freed from some contained Au by remelting and treating with Na_2CO_3 , sprinkling the latter on the surface of the molten chloride. Globules of Ag are reduced and sink to the bottom, carrying Au with them. The Au-free $AgCl$ is then treated with hot H_2O to remove Cu, which is sepd. from soln. by pptn. on Fe. The $AgCl$ is then reduced to Ag by contact with Fe plates in a HCl soln., and finally washed and melted. The fineness of the Au produced by the process will average 995; the Ag fineness varies from 995 to

998. The time required varies with the amt. of Ag and base metals present in the Au, e. g., an ingot weighing 500 oz. and containing 140 oz. base and 80 oz. Ag required 7 hrs. F. W. SMITHER.

Treatment of waste material containing silver. R. J. MARSH. *Metal Ind.* 13, 314-7(1915).—A detailed description of methods pursued by a large silver shop in recovering the precious metal. The proper sampling of such material before forwarding to the smelter is emphasized. The methods of collecting and burning sweepings, crushing, sifting, and sampling are described. The usual methods are also described for the treatment of filings and grindings and the recovery of Ag from acid solns. and old plating baths. F. W. SMITHER.

Lead acetate vs. litharge. C. R. MORRIS. *Eng. Mining J.* 100, 148(1915).—In expts. at the Mexican mill, Virginia City, Nev., it was found that there was not much difference in the mill between using 1 or 2 lbs. of Pb acetate. Using PbO instead of Pb acetate, putting it into the tube mill 3 times a day, gave as good an extn. Using 0.75 lb. of PbO in the tube mill and 0.25 lb. of Pb acetate in the agitators gave a better extn. Results are reported. F. W. SMITHER.

Treatment of arsenical-antimonial sulfide ore. K. B. MOORE AND H. R. EDMANDS. *J. Chamber Mines W. Australia*, Feb., 1915; *Mel. Chem. Eng.* 13, 508-9(1915).—A record of exptl. and practical work on the cyanide treatment of Au ore containing As and Sb sulfides. A representative analysis of the ore showed: insol. 70.04, Fe 8.3, Sb 0.21, As 0.96, S 5.62, CO₂ trace, MgO 2.74, Al₂O₃ 2.02, CaO 3.36, alkalis, H₂O, etc., 6.75%. Amalgamation and cyanidation yielded only about 50% of the Au. Concn. gave still poorer results, and the tailing yielded less than half its Au to cyanidation. Flotation gave disappointing results. CNBr was tried without success, and preliminary treatment with NaOH did not improve matters much, as some of the Au was associated with As and was not liberated. Expts. with roasting and cyaniding indicated that roasting was an essential, and a plant has been constructed in which the ore is dried, ground in a Krupp ball mill and roasted in an Edwards duplex furnace. After this treatment the ore is mixed with oxidized ore and given the usual cyanide treatment. Perfectly sweet roasting is not necessary in order to get a max. extn., but must be carried far enough to liberate all Au from the sulfide and leave no unaltered FeS₂ or arsenopyrite. Ore carrying 3.5 to 4% S retains from 0.5 to 1% after roasting, about 2/3 of which is sol. in Na₂CO₃. Samples taken half way down the roaster have given as good extn. as those taken from the discharge. The addition of Pb acetate is necessary to remove sol. sulfides. The roast cannot be tested satisfactorily by the ordinary I absorption method. Owing to the frequent presence in the roasted product of Sb, which seps. out on acidifying the Na₂CO₃ ext., I does not give a sharp end point. The method used is to boil 20 g. of ore in 100 cc. of 5% Na₂CO₃ for 1 min., decant 50 cc., acidify with H₂SO₄ and titrate with N/30 KMnO₄. If less than 10 cc. of KMnO₄ are required the roast is considered fair, but often a roast with far more reducing power gives quite as good extn. The loss of Au by volatilization rarely exceeds 3%. Plant soln. is tested for reducing power by acidifying 50 cc. and titrating with N/30 KMnO₄. Usually 25 to 50 cc. of KMnO₄ are decolorized. Fine grinding is essential to good extn., the av. screen test showing only about 15% plus 150 mesh. A thin pulp of about 35% solids gives better results than one of 45% solids. Zn shavings gave poor results for pptn. The authors devised a system of Zn dust pptn. that gave satisfactory results. The extn. has averaged over 84%, with a residue of 7s. per ton. Cyanide consumption does not exceed 1 lb. NaCN per ton. Total cost is 9s. per ton. F. W. SMITHER.

Notes on the metallurgy of zinc. E. H. LESLIE. *Mining Sci. Press* 111, 162-6

(1915).—A review and discussion of American and foreign practice. Statistics, cost data, etc., are given. F. W. SMITHER.

Leaching copper ore. W. L. AUSTIN. *Mining Sci. Press* 111, 199-200(1915); cf. C. A. 8, 3283.—A discussion of modern practice, pointing out the advantages of employing H_2S as a com. precipitant for Cu. F. W. SMITHER.

The Salida smelter. F. D. WEEKS. *Bull. Am. Inst. Mining Eng.* 1915, 1691-6. —A description of the copper smelting plant at Salida, Colo. H. L. OLIN.

Blast-furnace plant auxiliaries and general arrangement. J. E. JOHNSON, JR. *Met. Chem. Eng.* 13, 373-8, 429-39, 495-9(1915).—J. describes the system of water supply, including pumping machinery, standpipes, and water mains, and the connections from the water mains to the circulating system around the furnace, as well as the disposal of the foul waste water. The following other points are also discussed: Compressed air and elec. supply; production of dry blast by refrigeration and the calcs. incidental to the same; a diagram, showing the dry-blast plant designed by Frank C. Roberts & Co., single-stage, brine-circulation, non-regenerative; chart showing ratio of actual to theoretical h. p. required for refrigeration with different temp. ranges; total heat and temp. entropy diagram of air and water vapor; total heat temp. entropy diagram applied to detg. power for different methods of blast refrigeration; elevation diagram of Carrier dry-blast plant (ammonia compressors, motor-driven); plan of Carrier dry blast; diagram showing arrangement of cooling towers and regenerators in proper relation. J. then discusses the general arrangement of furnace plants, the distances of the furnaces apart, with a diagram of the general arrangement of the Federal Furnace Co.'s plant, and the general ground plan and track layout for the plant of the Indiana Steel Co. at Gary, Ind., and the general ground plan and elevation of a pair of furnaces with their stoves and dust-catcher at the same plant. Finally, the elevation of the furnace, the arrangement of the boilers and engines, the arrangement for the disposal of iron, and the disposal of slag are discussed. C. A. NOWAK.

Barth slide rule for pulp measurement. C. G. BARTH, JR. *Eng. Mining J.* 100, 228(1915).—This slide rule gives the contents, in tons, of tanks ranging in diam. from 10 to 36 ft. and in d. from 1 to 3. The rule consists of 4 scales—one giving the diam. of the tank by 6-in. intervals, a d. scale ranging from 1 to 3, a scale giving the % of H_2O from 20 to 90, and a scale giving the tons of 2000 lbs. Examples are given (with cuts) illustrating methods of use. F. W. SMITHER.

Low-pressure oil-burning metallurgical furnaces. ANON. *Met. Chem. Eng.* 13, 510-1(1915).—A description with illustrations of the low-pressure oil burner of the Case metallurgical furnaces manufactured by the Denver Fire Clay Co. Oil is introduced usually by gravity (although high pressure can be used), and issues from the central part of the burner in a cone spray diverging at an angle of 45° . All air for combustion goes through the burner, issuing from 2 annular rows of holes and forming a cone of jets converging at an angle of 60° . This produces an excellent mixt. of oil and air which enters the combustion chamber of the furnace through a small opening of the same size at the face of the burner, thus excluding auxiliary air. Both oil and air are under valve control. Air is supplied by a direct-connected motor-driven blower which runs at 3600 r. p. m. and delivers 3000 cu. ft. of air per min. at a pressure of about 6 oz. The fan has 20 blades of Al mounted in a cast Fe casing. *Advantages:* Freedom from noise, economy of fuel, control of air supply, perfect combustion without formation of C, and reduced wear and tear on the crucible and other parts of the furnace. The poor features involved in needle valves are entirely eliminated. The burner is applied to a variety of furnaces constructed for special purposes. The tilting type furnace is used for melting brass and other metals, refining cyanide ppts., and melting

Au and Ag bullion. Other types are used for the heat treatment of steel, for annealing and enameling, and for assaying. Results are given, showing economy of fuel and time, increased life of crucibles, etc., with these burners. F. W. SMITHER.

Gas blowing engines at the Steelton plant of the Pennsylvania Steel Co. *Met. Chem. Eng.* 13, 516-9(1915).—Each engine consists of 2 gas cylinders 46 in. diam. and an air cylinder 84 in. diam. in tandem. A detailed description with 5 illustrations.

W. L. BADGER.

Antimony and the war. ANON. *Engineering* 100, 43-5(1915).—A discussion of the supply, uses, methods of production, properties, prices, etc., of Sb and its compds. Its use and value as a hardener of Pb for munitions are briefly discussed. Statistics are given.

F. W. SMITHER.

U. S., 1,148,782, Aug. 3. W. D. KILBOURN. Reducing lead from its ores in a blast furnace with flux and fuel. The latter, *e. g.*, small coke, is coated with PbO in a sufficiently thick layer to prevent ignition of the fuel at its usual ignition temp. so that it is carried through the furnace to a zone of higher temp. before its ignition and reducing action takes place.

U. S., 1,148,814, Aug. 3. L. ADDICKS and C. L. BROWER. Nearly pure copper is further refined by melting under mildly oxidizing conditions with just sufficient acid material such as SiO₂ to slag off the small amt of impurities in the Cu and produce not more than 1% the wt. of the charge of slag. The molten charge is covered with a protecting layer of C and the firing is regulated so that ash does not come into contact with the charge. The small amt. of Cu oxide formed is poled out.

Brit., 21,738, Sept. 26, 1913. A. NIEWERTH (NEE VLIEX). Furnaces for reducing ores of the kind described in 18,327, 1897, in which a central shaft communicates through openings at different levels with side chambers, and in which means are provided for forcing a current of reducing-gas in either direction through the app. Cf. C. A. 8, 2669.

Brit., 21,807, Sept. 27, 1913. E. FRITSCH. A composition for use in coating metal plates, etc., with aluminium or its alloys, consists of finely divided coating-metal, a readily fusible alloy such as soft solder or a metal such as Sn, capable of acting as a solder, and a resinous or carbonaceous flux, the whole being rendered plastic by the use of a vehicle such as turpentine. An even layer of the paste is applied to the surface of the metal, which is subjected, after drying, to a temp. of about 220° in a muffle under the protection of H, coal-gas, or N. An alloy containing 14 parts of Sn, 3 of Pb, and 1 of Bi, may be used with Al; Al alloys containing also Mn, W, or other hardening-metals, may be used.

Brit., 7,927, Mar. 28, 1914. W. H. KELLY and P. J. MORAN. In mfg. alloys of metals having substantially different m. p., such as alloys of Cu with Fe and steel, or Pb, the metals are subjected before admixt. to the action of O and H. For this purpose, steam from a boiler passes through a superheater wherein it is partly or entirely dissociated, and is then conveyed through a flexible pipe and a nozzle into each of the molten metals. A Cu-steel alloy obtained in this way is suitable for use in sheathing ships; a Cu-Fe alloy for knives; and a Cu-Pb alloy for journal boxes.

Brit., 7,928, Mar. 28, 1914. G. BENSL. Soldering aluminium or its alloys to each other or to Cu, brass, Ag, or Pb, by a solder consisting of Cd 13, Sn 1, and Zn 6 parts.

Brit., 8,270, Apr. 1, 1914. G. A. JOYCE. Alloys of Cu, Ni, and Al, with or without steel, are used for mounting diamonds for industrial purposes, or for making golf clubs. The % comps. of the alloys are as follows: Cu 80.5, Ni 17.06, and Al 2.44; Cu 27.5, 35, and 40, Ni 65, 50 and 45, steel 5, 10 and 10, and Al 2.5, 5 and 5, respectively.

Brit., 8,384, Apr. 2, 1914. W. K. BARTSCH. In sintering ores, etc., a layer of ignited fuel carried by an endless chain grate or like support is brought under a hopper to receive a superposed layer of ore, and air is passed upwards through the layers from an air-box. Several layers of ore may be deposited in succession, and fuel may be mixed with the ore or not. A scraper transfers the sintered charge to a chamber, and gases escape through flues. Cf. C. A. 9, 292.

Brit., 8,611, Apr. 4, 1914. A. RICHARDS. In the treatment of tin ores by the processes described in 26,644, 1911 (C. A. 7, 1789) and 56, 1912 (C. A. 7, 2099), in which the ore is heated with a reducing agent and a solid Cl- or Br-bearing substance, the reaction is effected at about 800° (750-850°) in a reducing or non-oxidizing atm. The charge is prevented from agglomerating into large impervious masses by stirring in a muffle furnace, or by using a rotary furnace, or by showering the granular material in a shaft furnace, producer, or gas oven, against ascending gas and flame, or by treating the charge in thin slabs or blocks. In the last case, after the extn. of the Sn, the temp. may be raised to convert the residue into building bricks or slabs or other com. forms. The extn. of the fume is facilitated by maintaining a reduced pressure within the furnace.

Ger., 283,075, Aug. 6, 1912. E. O. LEGGET, GEB. HOLMAN. In a process of refining aluminium, the Al is heated in the presence of such an amt. of H₂SO₄ and KClO₃ that after the formation of O and Cl sufficient K₂SO₄ results to take up the products due to the action of the gases on the impurities in the Al. The Al is placed in a refractory, acid-proof vessel, and H₂SO₄ and KClO₃ are added. The materials are then heated until the Al is liquid, and the mixt. is stirred vigorously to insure contact of the chemicals with all parts of the metal. The mass is then allowed to stand for a time, until the impurities collect upon the surface. The Al is finally drawn off in the pure state, while the dross remains in the vessel. To 1 kg. Al in the form of a thin plate, about 35 g. H₂SO₄ and 70 g. KClO₃ are used. Almost pure Al is obtained; under ordinary conditions it does not oxidize, and may be used for welding. For this purpose it is alloyed with a mixt. of equal parts of Sn and Pb. Sn 12, Pb 12 and Al 2 parts are used. The metals are fused and poured into stick form. The resulting solder can be used without flux.

Furnace for the manufacture of steel, comprizing a plurality of metallic containers, built up to form the furnace, and containing cores of a basic or neutral material, or a mixt. of both. Magnesite, dolomite, and lime are mentioned, magnesite being preferred. Also, chromite, bauxite, and C can be used. The magnesite is burned, the resulting oxide is ground to a powder, rendered plastic with H_2O , and applied in that state. Cf. C. A. 8, 3286.

Ger., 283,548, July 26, 1913. I. A. LOSNER GEB. DIETSCH. Detinning tin-plate with the aid of oxide salt solns. Heretofore such processes have proved unsatisfactory, inasmuch as most of the salts used act upon the Fe as well as upon the Sn, and therefore the sepn. is rendered difficult. To overcome this objection, satd. aq. solns., instead of dil. solns., of such salts are employed. These satd. aq. solns. of oxide salts (sulfate or chloride of Fe, $SnCl_2$, $CuCl_2$, $SnSO_4$, or solns. of Fe_2O_3 or SnO_2 in satd. aq. solns. of Fe or Sn oxide salts), have the property of hardly attacking the Fe while almost instantly dissolving the Sn. The same action is secured when the active oxide solns. are satd. with indifferent salts, such as Na_2SO_4 , $CaCl_2$, and the like. The cleaned tin-plate is immersed in a satd. aq. soln. of $SnCl_4$, whereupon the detinning process sets in immediately. The detinning soln. is somewhat dild. by the H_2O from the wet scrap, but dissolved Sn is added at the same time, so that the soln. remains almost constant as to concn. The $SnCl_2$ formed is converted, from time to time, by means of Cl or HCl and air, into $SnCl_4$. An excess of free Cl and HCl is to be avoided.

Ger., 284,067, Aug. 29, 1911. Addition to 282,899 (C. A. 9, 2378). E. FRITSCH. In coating sheet metal with aluminium, the welding paste specified in the principal patent is prepd. with the aid of the low m. alloys of Bi. Mn powder may be added to the powdered alloy. Wax or copal may be used as binders, but especially

organic substances whose vaporization point is higher than that of the metal alloy, but lower than that of Al. About 10-15 parts Bi or Bi alloy are used to 100 parts Al. The flux consists, e. g., of Al 100, Bi 25, Sn 2, Pb 0.5, Mn 1.5 parts, with copal soln. as binder.

10. ORGANIC CHEMISTRY.

C. A. ROULLER.

Leuco derivatives of indigo dyes and their etherification. M. CHILIKIN. *J. Russ. Phys. Chem. Soc.* 47, 539-52 (1915).—In continuation of his work on indigo (C. A. 8, 912) C. made the following compds.: Methylquinolindigo, $\text{HO} \text{CMe} \cdot \text{C}_6\text{H}_4 \cdot \text{NH} \cdot \text{C} \text{:-}$

C.NH.C₆H₄.CO, prepd. by the action of Me_2SO_4 on the Na salt of leucoindigo

in a H atm., cryst., transparent in transmitted and almost black in reflected light, m. about 209° , decomp. 235° , colored olive-green by H_2SO_4 , difficultly sol. in all solvents, volatile, giving indigo-like vapors. Ethylquinolindigo (not perfectly pure) made with EtI instead of Me_2SO_4 , light powder of a dark color, m. about 216° (decompn.), forms a bright yellow zinc salt which gives with MeOH containing some H_2SO_4 a dark soln. from which H_2O ppts. a black powder. Amylquinolindigo, made with AmBr, bluish green powder, m. $160-2^\circ$, dissolves in MeOH with reddish and in H_2SO_4 with bluish green color. Benzylquinolthioindigo, $\text{PhCH}_2\text{C}(\text{OH}) \cdot \text{C}_6\text{H}_4 \cdot \text{S} \cdot \text{C} \text{:-}$

C.S.C₆H₄.CO, made by the action of $\text{Me}_2\text{Ph}(\text{PhCH}_2)\text{NCl}$ on the Na salt of leucothio-

indigo (a), microcryst. reddish powder, m. $56-7^\circ$. Ethylquinolthioindigo ethyl ether, made by the action of EtI on (a), crystals, m. $145-6^\circ$, is colored dark orange by H_2SO_4 . Benzyl ether, made with PhCH_2I instead of EtI, very small rose-colored crystals, m. $211-1.5^\circ$. By the interaction of EtI with the Na salt of leucothioindigo-scarlet R (b) a compound was obtained whose formula is either $\text{EtOCEt} \cdot \text{C}_6\text{H}_4 \cdot \text{S} \cdot \text{C} \text{:-}$ $\text{C} \cdot \text{C}_6\text{H}_4 \cdot \text{NH} \cdot \text{CO}$

or $\text{CO} \cdot \text{C}_6\text{H}_4 \cdot \text{S} \cdot \text{C} \text{:-}$ $\text{C} \cdot \text{C}_6\text{H}_4 \cdot \text{NH} \cdot \text{CEtOEt}$, colorless crystals, m. 166.5° , while PhCH_2Cl

gave with (b) a compound of similar structure, microcryst., bright yellow powder, m. $198.5-200^\circ$. The Na salt of leucothioindigo-scarlet 2G gave with EtI the compound $\text{EtOCEt} \cdot \text{C}_6\text{H}_4 \cdot \text{S} \cdot \text{C} \text{:-}$ $\text{C} \cdot \text{C}_{10}\text{H}_6 \cdot \text{CO}$, microcryst. orange powder, m. $194-5^\circ$.

H. M. GORDIN.

Halogen derivatives of the hydrocarbons of the diphenylmethane group. A. M. NASTYUKOV AND V. F. ANDREEV. *J. Russ. Phys. Chem. Soc.* 47, 552-8 (1915).—Using N.'s method (C. A. 3, 637), 3,3-dichlorodiphenylmethane, $\text{CH}_2(\text{C}_6\text{H}_4\text{Cl})_2$, was prepd. by treating PhCl with HCHO in presence of H_2SO_4 and decomp. the resulting formolite by heat (yield 15%), heavy, almost colorless, slightly fluorescent liquid, b. $317-8^\circ$, d_{21}^{21} 1.2336, $n_{19.4}^{19.4}$ 1.5948, solidifies in a freezing mixt. and then m. 8° , gives upon oxidation with CrO_2Cl_2 a dichlorobenzophenone m. $126-7^\circ$, whose oxime m. $132-3^\circ$. By the same method o- and p-MeC₆H₄Cl gave the corresponding dichloroditolylmethanes, the compd. from the o-isomer being a liquid, b. $340-3^\circ$, not solidifying upon cooling, d_{20}^{20} 1.2232, $n_{19.7}^{19.7}$ 1.59, and giving upon oxidation a dichlorotoluphenone m. $132-3^\circ$, while the compd. from the p-isomer b. 205° and solidifies on cooling to needles m. 42° . With p-C₆H₄Cl₂ the reaction did not go, even in presence of much H_2SO_4 . H. M. G.

Isomerization of cyclic compounds. N. A. ROZANOV. *J. Russ. Phys. Chem. Soc.* 47, 591-610 (1915).—With a view to detg. the regularities of isomerization of cyclic compds., cyclopentanol (a) was subjected to several reactions. When treated

with HI (a) was not isomerized, the product being cyclopentyl iodide (b). With AgNO_2 the latter gave NO, HCN (whose formation is difficult to explain), cyclopentyl nitrite, small amts. of what seemed to be $\text{CH}_3\text{CH}_2\text{CH}_2\text{C}:\text{CH}_2$ (c) (not examd. as such but as

the dibromide $\text{C}_5\text{H}_8\text{Br}_2$) and $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CHNO}_2$, and considerable amts. of

$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{C}(\text{NO})\text{NO}_2$ and 1,1-methylnitrosotetramethylene $\text{CH}_3\text{CH}_2\text{CH}_2\text{CMeNO}_2$

(d), b_{10} 80–2°, d_4^{20} 1.0795, n_D^{20} 1.4589. Attempts to reduce (d) to an amine, in order to change the latter to the corresponding alc., failed, the reduction (with Sn + HCl) completely destroying the ring with formation of NH_4Cl and volatile hydrocarbons. By Grignard's method (b) was converted into cyclopentylcarbinol (e), and this by means of HI into $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CHCH}_2\text{I}$. The latter, upon treatment with AgNO_2 ,

gave a small amt. of $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CHNO}_2$ (f), and considerable amts. of

$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CMeNO}_2$ and cyclopentylnitromethane, $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CHNO}_2$,

liquid, b_{10} 110°, d_4^{20} 1.0713, n_D^{20} 1.4587. When (e) is treated with $(\text{CO}_2\text{H})_2$ the product is not $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{C}:\text{CH}_2$, but its isomer $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}:\text{CH}$ (g) which

upon oxidation gives $(\text{CH}_2\text{CH}_2\text{CO}_2\text{H})_2$. The formation of (c), (d), (f) and (g) shows that, contrary to Baeyer's opinion, the 5-membered ring is as capable of isomerization as other rings, and that isomerization may be produced not only by acids, but even by such mild reagents as AgNO_2 . The isomerization of the 5-membered ring is subject to the same regularities as that of other rings, namely, in the presence of a side-chain the resulting ring contains the 1 C atom more, while in the absence of a side-chain it contains 1 C atom less than the original ring. Raising the reaction temp. facilitates isomerization, while lowering the temp. retards it. Several of the compds. isolated in this work were examd. spectroscopically.

H. M. GORDIN.

Condensation of β -diketones with diamines. Preliminary communication. N. A. ROZANOV. *J. Russ. Phys. Chem. Soc.* 47, 611–3 (1915).—Treated with $(\text{CH}_2\text{NH}_2)_2$, CH_3Ac_2 yields a cryst. compound m. 112–3°, while MeCHAc_2 yields a cryst. compound m. 154–5°. Both are easily sol. in H_2O , difficultly sol. in alc. or Et_2O . Assuming the above diketones to react in the enol form, the constitutions of the 2 compds. are supposed to be resp. $\text{MeC}:\text{CH.CMe}:\text{N.CH}_2\text{CH}_2\text{NH}$, and $\text{MeC}:\text{CMe.CMe}:\text{N.CH}_2\text{CH}_2\text{NH}$.

Further exam. of these and similar reaction products of diketones with diamines are under way.

H. M. GORDIN.

Interaction of dehydrobenzoylacetic acid with ammonia, amines and other nitrogen bases. IV. SHETTLÉ. *J. Russ. Phys. Chem. Soc.* 47, 645–79 (1915).—When $\text{PhC}:\text{CH.CO.CHBz.CO.O}$ (a) interacts in the cold with NH_3 or its derivs. RNH_2 , the

anhydride O of (a) is replaced by NR (R = H when NH_3 is used), and the general formula of the resulting products is $\text{PhC}:\text{CH.CO.CHBz.CO.NR}$ (b). This formula,

better than any other, accounts for the fact that both concd. HCl and concd. KOH convert the reaction product of (a) and NH_3 into $\text{PhC}:\text{CH.CO.CH}:\text{CPh.NH}$ (c).

In the case of concd. HCl this conversion is direct, while with concd. KOH the acid $\text{PhC}:\text{CH.CO.C}(\text{CO}_2\text{H}):\text{CPh.NH}$ (d) is formed intermediately, this by the action of heat

losing CO_2 and changing to (c). When R in (b) is not H, the reaction with concd.

HCl or concd. KOH is slightly different, the latter completely decomp. (b), while the former gives (c) instead of the expected NR compd., the R being eliminated as ROH. Entirely different is the reaction of (b) with very dil. HCl or KOH. In these cases (a) is regenerated. It is supposed that with dil. acid or alk. $\text{PhC(OH):CHCOCHBz-CONHR}$ appears as intermediate product. The mutual displacement of NH_3 and its derivs. (according to which of them is in excess), previously observed for those compds. of formula (b) in which R is either H or Me (C. A. 6, 1602), was found to hold good for all the compds. of formula (b) described in this work, except that in which R is $\text{NH}_2\text{-CONH}$, obtained by the interaction of (a) with $\text{NH}_2\text{CONHNH}_2$. While the latter is capable of driving out NH_3 and all of its derivs. from (b), it is itself not displaceable by these, with the exception of PhNHNH_2 and NH_4OH . This mutual displacement of NH_3 and its derivs. in heterocyclic N compds. does not seem to be a perfectly general reaction. Thus it does not take place with $\text{MeC:CH.CO.CHAc.CO.NPh}$

(Tzonev and Petrenko-Kritchenko, C. A. 7, 3966) or with the esters of $\text{PhC:C(CO}_2\text{H).CO.C(CO}_2\text{H):CPh.NH}$ (unpublished work by V. Iv. Shtvan). When

the interaction of (a) with NH_3 or its derivs. takes place in sealed tubes at an elevated temp., entirely different substances result. Thus while with a large excess of NH_3 (a) gives a (b) in which R is H, with a limited amt. of it there is elimination of BzOH and formation of the compound $\text{PhC:CH.CO.CH}_2\text{.CO.NH}$

(e), while MeNH_2 gives the compound $\text{MeNHCPh:CHCOC(:CPhNHMe)-C(NHMe)_2OH}$ (f), and EtNH_2 gives the compound $\text{EtNHCPh:CHCOC(:CPhNHEt)-C(NHEt)_2OH}$ (g). With PrNH_2 and PhCH_2NH_2 at a high temp. (a) also enters into reaction, but no definite compds. could be isolated from these reaction products. The latter are rich in N, and will be examd. later. With secondary amines in the cold (a) or (b) did not react. At a high temp. they reacted with Me_2NH to form the compound $\text{Me}_2\text{NCPH:CHCOC(:CPhNMe}_2\text{)CONMe}_2$ (h), while with Et_2NH the reaction product yielded nothing definite. When Et_2NH was used in limited amts. and the reaction temp. not permitted to rise above $110\text{--}20^\circ$, its reaction product with the (b) in which R is H yielded a small amt. of (a). Evidently Et_2NH reacts in this case like very dil. KOH. With Ph_2NH (a) could not be made to react under any conditions. The new compounds (b) described in this work are as follows: *Ethyl* (R = Et), m. $172\text{--}3^\circ$, gives some diphenylpyrone when heated with concd. HCl. *Propyl*, m. $147\text{--}7.5^\circ$. *Isopropyl*, m. 180° . *Butyl*, m. 114° . *sec-Butyl*, m. 167° . *Isobutyl*, m. 167° . *Amyl*, m. 118° . *Isoamyl*, m. $125\text{--}6^\circ$. *Heptyl*, m. $83\text{--}4^\circ$. *Allyl*, m. $143\text{--}4^\circ$. All of the above compds. are not colored by FeCl_3 . *Phenyl*, m. $203\text{--}4^\circ$, is colored red by alc. KOH or by standing in contact with FeCl_3 . *Benzyl*, m. $172\text{--}3^\circ$. *Phenylethyl*, (R = PhCH_2CH_2), m. $150\text{--}0.5^\circ$. *o-Tolyl*, m. $200\text{--}1^\circ$. *m-Tolyl*, m. $212\text{--}4^\circ$. *p-Tolyl*, m. $202\text{--}3^\circ$. *α-Naphthyl*, m. $215\text{--}6^\circ$. *β-Naphthyl*, m. $243\text{--}4^\circ$. *Diphenylamino* (R = Ph_2N), golden yellow crystals, m. $160\text{--}1^\circ$, turning red. *Carbamino* (R = $\text{NH}_2\text{-CONH}$), m. 180° , and has acid properties. This compd. differs from the preceding ones in 2 points. With concd. KOH it gives, with elimination of $\text{NH}_2\text{CO}_2\text{H}$, the salt $\text{PhC:CH.CO.C(CO}_2\text{K):CPh.NNH}_2$ which is decompd. by acids with formation of the

lactam $\text{PhC:CH.CO.C:CPh.N.NH}$, m. $160\text{--}1^\circ$, while with very dil. KOH it yields a

very small amt. of this lactam, most of it remaining unchanged. The compound $\text{PhC:CH.CO.CH(CPh:NOH).CO.NOH}$, from free NH_4OH and either (a) or (b), m. 151--

2° , is colored violet-red by FeCl_3 , has acid properties, being sol. in KOH and in NH_4OH ,

forms a *silver salt*, $C_{18}H_{15}O_4N_2Ag_2$, is not affected by hot HCl under ordinary pressure, but is completely decompd. by it in a sealed tube. With $NH_2OH.HCl$ (a) and (b)

interact to form 2 substances: (x) the compound $PhC:CH.CO.C:CPh.O.N.CO$,

needles, m. 218° , insol. in aq. alkalis, not colored by $FeCl_3$, is completely decompd. by heating with HCl in a sealed tube, and is converted by concd. alc. KOH, with elimination of BzOH, into the compound $PhC:CH.CO.CH_2.CO.NOH$, m. $182-3^\circ$, gives a

slight coloration with $FeCl_3$, and forms a *silver salt*, $C_{17}H_{13}O_3NAg$, and an unstable *acetate*. (2) The compound (I), m. 193° , is colored dark blue by $FeCl_3$, gives a *potas-*

sium salt, m. $232-3^\circ$, a *silver salt*, $C_{18}H_{11}O_3N_2Ag$, and an *acetate*, $C_{20}H_{14}O_4N_2$, m. 178° , and yields with HCl at 170° α -phenazyl- γ -phenylisoxazole, $BzCH_2C:CH.CPh:N.O$

(i), cryst., m. 90° , is not colored by $FeCl_3$, gives an *oxime*, m. 148° , but no hydration. Instead of the latter (i), when treated with $PhNHNH_2$, changes to the corresponding *pyrazole derivative* $BzCH_2C:CH.CPh:N.NPh$, m. 169° . Upon oxidation

(i) yields BzOH and γ -phenylisoxazole- α -carboxylic acid, $HO_2C.C:CH.CPh:N.O$, m.

$177-8^\circ$. With either $PhNHNH_2$ or $PhNHNH_2.HCl$ (a) and (b) react to form the compound (II), m. $268-9^\circ$, is colored by alc. KOH, but not by $FeCl_3$, is not affected by heating to nearly 200° with HCl or KOH. With N_2H_4 (I) and (II) react to form the compound (III), m. $280-1^\circ$, is colored dark brown by $FeCl_3$, and withstands heating with HCl or KOH. Contrary to the statement of Rotenburg (*Ber.* 27, 790), no trace of phenylpyrazolone is produced in his reaction. (d) m. $243-5^\circ$, is insol. in all solvents, except AcOH or alkali or alk. carbonates. The (d) described by Feist (*Ber.* 23, 3734) must have been impure. (e) m. $244-5^\circ$, is not colored by $FeCl_3$, withstands heating with acids or alkalis, and does not react with NH_2OH , $PhNHNH_2$, or amines, showing that with the disappearance of a side-chain from (b) the mol. acquires greater stability, so that no displacement of NH_2 by amines can take place. (b) m. $116-8^\circ$, gives a dark blue color with $FeCl_3$, and reacts with NH_2OH with elimination of $MeNH_2$ and formation of the compound $PhC:CH.CO.CH(CPh:NOH).CO.NOH$, m. $151-2^\circ$, and gives a dark

red color with $FeCl_3$. With $PhNHNH_2$ (b) reacts to form the compound $PhC:CH.CO.CH(CPh:N.NHPh).CO.N.NHPh$, m. $137-8^\circ$, is colored reddish by alc.

KOH. (g) m. $92-4^\circ$, gives a dark color with $FeCl_3$, and behaves with NH_2OH and $PhNHNH_2$ like (f). (h) m. $218-9^\circ$, is not colored by $FeCl_3$, gives a *hydrochloride*, m. $228-30^\circ$, and a *chloroplatinate*, $(C_{24}H_{21}O_2N_3)_2.4HCl.2PtCl_6$, and does not react with NH_2OH , $PhNHNH_2$, or amines. Heated with HCl in a sealed tube (h) changes, with elimination of BzOH, to the compound $Me_2NCPh:CHCOCH_2CONMe_2$, m. $208-10^\circ$; *chloroplatinate*, $(C_{18}H_{20}O_2N_3)_2.2HCl.PtCl_6$.

H. M. GORDIN.

Addition of hydrogen to acetylene derivatives. V. Hydrogenation of tetraethylbutindiol. YU. S. ZAL'KIND AND N. K. BUISTRYAKOV. *J. Russ. Phys. Chem. Soc.* 47, 680-8 (1915).—Tetraethylbutindiol, $[Et_3C(OH)C:]_2$ (a), was made by acting with Et_3CO on $(BrMgC:)_2$ and decomp. the product with dil. H_2SO_4 . Solns. of (a)

in Et_2O were hydrogenated in presence of Pd black or Pt black as catalyzers, and the amts. of H consumed after definite time intervals detd. By varying the amts. of catalyzer and the concn. of the solns. the influence of these factors for each of the catalyzers on the value of the velocity const. (k) of the reaction of addition of H to (a) was studied. For calcg. (k) the usual equation for monomol. reactions was used. The diagrammatic and profusely tabulated results may thus be summarized: Both with Pd and Pt the hydrogenation of (a) is a slow process, and is slower with the former than with the latter. With Pt the values of (k), within wide limits, are almost proportional to the amts. of catalyzer used, while with Pd, down to a certain limit, its amt. has no influence on the value of (k). With a very small amt. of Pd (0.005 g.), however, the value of (k) becomes very small. With larger amts. of Pd (k) continually increases until 90% of the required amt. of H (4 atoms) has been added, while with 0.005 g. (k) begins to decrease after 50% of the required H has been consumed. With Pt (k) is comparatively large until 50% of the required H has been added, and then gradually drops until 90% of it has been consumed. This is ascribed to a reduction of the OH of (a) which, being very slow, does not effect (k) before the addition reaction approaches completion. The following compds. were obtained in the course of the work: *Tetraethylbutanediol*, $[\text{Et}_4\text{C}(\text{OH})\text{CH}_2]_2$, crystals, m. $66-7.5^\circ$, gives a liquid acetate of an agreeable odor, and is converted by H_2SO_4 into the oxide $\text{C}_{12}\text{H}_{24}\text{O}$, liquid of agreeable odor, b. $204-6^\circ$, b₁ $89-90^\circ$. *Tetraethylbutenediol*, $[\text{Et}_4\text{C}(\text{OH})\text{CH}]_2$, odorless crystals, m. $77-8.5^\circ$, is not appreciably colored by H_2SO_4 . VI. Hydrogenation of dimethyldiphenylbutindiol. YU. S. ZAL'KIND AND K. V. KVAPISHEVSKII. *J. Russ. Phys. Chem. Soc.* 47, 688-703 (1915).—Expts. similar to those recorded above were made with the 2 inactive stereoisomers (a), m. 163° , and (b), m. $125-7^\circ$, of $[\text{MePhC}(\text{OH})\text{C}]_2$ (Dupont, *Compt. rend.* 155, 1121). The results, given in the tables and curves, may thus be summarized: With colloidal Pd (a) is less readily hydrogenated than (b), while with Pt black the reverse is the case. With a given amt. of catalyzer the value of the velocity const. (k) is fairly const. for (b) while for (a) it gradually decreases as the hydrogenation progresses. With certain amts. of catalyzer (k) was not const. at all. While acknowledging their inability to explain the inconstancy of (k), Z. and K. are nevertheless reluctant to admit the applicability of Orlov's insufficiently tested modified equations (Khar'kov, "Kinetics of Chem. Reactions and Catalysis," 1913), which he claims (in private correspondence) would give more const. values of (k) than the equation used by them. Within certain limits the values of (k) are nearly proportional to the amts. of catalyzer used, particularly in the first stages of hydrogenation. With both Pd and Pt the hydrogenation slackens after H_2 has been added for 1 mol. of (a) or (b), and this slackening is more pronounced with Pd than with Pt. The compds. obtained in this work are as follows: *Dimethyldiphenylbutenediol*, $[\text{MePhC}(\text{OH})\text{CH}]_2$ (c), from either (a) or (b). The (c) from (a) m. $97-102^\circ$, colors H_2SO_4 yellowish, and gives upon bromination in CHCl_3 the bromide $\text{C}_{18}\text{H}_{18}\text{BrO}_2$, m. 161° , as sole product, showing this (c) to consist of only 1 of its 2 possible stereoisomers. Other attempts to resolve this (c) into optical antipodes also failed. Prolonged boiling with 15% H_2SO_4 failed to convert this (c) into an oxide. The (c) from (b) m. 110° , gives the same color with H_2SO_4 as the other (c), but is much more readily sol. in Et_2O , and is easily changed by dil. H_2SO_4 to the oxide $\text{C}_{10}\text{H}_{18}\text{O}$, liquid of agreeable odor. The fact that the latter is the sole product in this reaction shows that this (c), too, wholly consists of only 1 of its 2 possible stereoisomers. Expts. proved that hydrogenation of (b), even without using any catalyzer, also yields the (c) m. 110° . *Dimethyldiphenylbutanediol*, $[\text{MePhC}(\text{OH})\text{CH}_2]_2$ (d), from either (a) or (b). The (d) from (a) m. 142° , while that from (b) m. 154° . The (d) from (b) gave, upon boiling with dil. H_2SO_4 , the oxide $\text{C}_{18}\text{H}_{20}\text{O}$, m. 72° .

H. M. GORDIN.

Syntheses with the aid of acetylene. Preliminary communication. A. E. CHICHIBABIN. *J. Russ. Phys. Chem. Soc.* 47, 703-13(1915).—With a view to studying the condensation of hydrocarbons of the C_2H_2 and the C_2H_4 series and their union with nonmetals and their compds., C. examd. the reaction of C_2H_2 and C_2H_4 with NH_3 , H_2O , H_2S or S at high temps. in presence of Al_2O_3 , Cr_2O_3 , Fe_2O_3 , Fe , ZnO , NiO , TiO_2 , ThO_2 , SiO_2 , kaolin and $AlPO_4$, as catalyzers. The condensation of C_2H_2 alone under these conditions was also studied. The results were as follows: The reaction between C_2H_2 and NH_3 in presence of catalyzers takes place at a comparatively low temp. (300°). The product consists of pyrrole, α - and γ -picolines, the collidines $AcH \cdot NH_3$, and H. Pyridine itself or its homologs with an uneven number of C atoms in the mol. are not formed in this reaction. Under the same conditions, C_2H_4 gives with NH_3 the same products as C_2H_2 , but the temp. must be higher. It is possible that the high temp. changes first the C_2H_4 to C_2H_2 . With H_2S or S, C_2H_2 gives at a comparatively low temp. thiophene as chief product, together with its homologs containing an even number of C atoms in the mol. The reaction is suitable for making thiophene on a large scale, and it gives a purer product than that of Steinkopf and Kirchoff (*C. A.* 7, 538). Expts. with AcH showed that under the same conditions it gives the same products as C_2H_2 . Hence it may be assumed that either the AcH first loses H_2O , changing to C_2H_2 , or that the latter, in the unavoidable presence of traces of H_2O , changes first to AcH . With BzH and NH_3 , AcH gave α - and γ - PhC_2H_4N . The formation of AcH from C_2H_2 was discovered long ago by Kuchеров, though Gruenstein lately was given a patent for the method. (Cf. *C. A.* 8, 790.)

H. M. GORDIN.

Cryoscopic investigation of the combinations of dimethylpyrone with acids. V. A. PLOTNIKOV. *J. Russ. Phys. Chem. Soc.* 47, 730-7(1915).—In order to det. with how many mols. of acid 1 mol. of dimethylpyrone (a) is able to form salts, f.-p. detns. were made on (a) in C_6H_6 to which varying amts. of either CCl_3CO_2H or CBu_3CO_2H were added. The results showed that (a) forms 3 types of salts with these acids: (a).(b) (b = acid), (a).2 (b), 2(a).(b). The salts of the 1st type dissolve without decompn.; those of the 2nd are partly dissociated into (a) and salts of the 1st type; those of the 3rd are dissociated to a considerable extent.

H. M. GORDIN.

Dihydroresorcinols and their reduction. A. E. USPENSII. *J. Russ. Phys. Chem. Soc.* 47, 738-51(1915).—The following reduction products of $CH_3.CO.CH_2.CH_2.CO$

(a) and its derivs. are described: Cyclohexane-1,3-diol, $CH_3.CH(OH).CH_2.CH_2.CH_2.CH_2OH$

(by Zelinskii and Chervyakov, private communication), b_{11} $138-41^\circ$, gives an *acetate*, b_{11} $127-8^\circ$; 1,1,2-trimethylcyclohexane-1,3-diol, from $Me_3C.CHMe.CO.CH_2.CO.CH_3$

(b), crystals of a bitter-sweet taste, m. 149° ; 5-phenylcyclohexane-1,3-diol, from $PhCH.CH_2.CH(OH).CH_2.CH(OH).CH_2$ (c), crystals of a bitter-sweet taste, m.

160° . If yields be taken as criterion of facility of reduction, the following arrangement will represent a descending series in respect to this facility: 1,1-dimethylcyclohexane-1,3-diol (Zelinskii and Uspenskii, *C. A.* 7, 3600), (c), (a), (b). Attempts to reduce $MeCH.CH_2.CO.CH_2.CO.CH_2$ were not successful, chiefly because it could not be

obtained in sufficient amt. The above arrangement shows that no relation exists between facility of reduction and number of Me groups. Some relation can be noticed between reducibility and hydrolyzability, the more readily reducible compds. in this series being the least hydrolyzable. This rule fails, however, in the case of (c).

H. M. GORDIN.

Racemization of phenyl-*p*-tolylacetic acid. ALEXANDER MCKENZIE AND SYBIL T. WIDDOWS. Univ. Coll., Dundee, and Birkbeck Coll., London. *J. Chem. Soc.* 107, 702-15 (1915).—A modification of Gyr's method (*C. A.* 3, 650) was used for the prepn. of *dl*-4-MeC₆H₄CHPhCO₂H (*A*), which, when crystd. from dil. AcOH, m. 115-6°. One mol. (*A*) in boiling EtOH was heated with 1 mol. cinchonidine. The mixt. when allowed to cryst. in an ice chest yielded the *cinchonidine d*-phenyl-*p*-tolylacetate, needles (after 6 recrystns. from EtOH), m. 204-5° (decompn.), $[\alpha]_D^{16}$ in CHCl₃ -35°; this, when shaken with an excess of dil. H₂SO₄ and extd. with Et₂O, yielded *d*-phenyl-*p*-tolylacetic acid (*B*), feathery needles from dil. AcOH, m. 83-4°, $[\alpha]_D$ in acetone 14.6° (the influence of temp. between 12° and 33° being very slight). The *l*-rotatory mother liquors from the 1st crystns. of the (*B*) cinchonidine salt were acidified, the products united, dissolved in EtOH and treated with quinine. The *quinine salt* of the *l*-acid after a long series of crystns. finally yielded a fairly pure *l*-phenyl-*p*-tolylacetic acid (*C*), $[\alpha]_D$ -13.9°, the difficulty in purification being probably due to the formation of mixed crystals of the quinine salts of (*B*) and (*C*). (*B*) when heated at 100° with an excess of aq. KOH undergoes partial racemization, yielding upon acidification a mixt. of acids, $[\alpha]_D$ in acetone 9.1°. 1 mol. of (*A*) when heated at 150° for 3 hrs. with 4.5 mols. *l*-menthol in the presence of H₂SO₄ yielded a mixt. of *d*- and *l*-menthyl esters, the *l*-ester being slightly in excess, as shown by the polarimetric exam. of the residual unesterified acid, which instead of, being the inactive (*A*) showed a slight *d*-rotation. A 75% yield of *l*-menthyl *dl*-phenyl-*p*-tolylacetate (*D*), b₁₂ 250°, rectangular needles from aq. alc., m. 54-5°, $[\alpha]_D^{16}$ in acetone -59.2°, was obtained by converting (*A*) into the acid chloride and treating the latter with *l*-menthol in the presence of PhH and C₆H₅N. On submitting (*D*) to fractional sapon. 3 different fractions, all feebly *l*-rotatory, were obtained. The *l*-menthyl ester of (*B*), needles, m. 53-4°, $[\alpha]_D^{14}$ in acetone -53°, incompletely sapond. when boiled for 1.3 hrs. with a slight excess of alc. KOH, the fraction of ester remaining unsapond. having a somewhat higher $[\alpha]_D$ than the original ester, indicating that the ester had suffered catalytic racemization prior to sapon. The sapond. portion yielded the *dl*-acid (*A*). Similarly the *l*-menthyl ester of (*C*), m. 57-8°, $[\alpha]_D$ not given, yielded (*A*) upon sapon. *l*-Bornyl ester of (*A*), bright blue oil when freshly distd., b₁₂ 249°, on fractional sapon. yielded (practically inactive) (*A*). *l*-Bornyl ester of (*B*), b₁₂ 240°, when heated with a slight excess of alc. KOH yielded (*A*). If the sapon. was carried out at room temp. during 7 days, the recovered acid was very slightly *d*-rotatory. *d*-4-MeC₆H₄CHPhCO₂Et, m. 39-40° (cf. Zincke, *Ber.* 10, 997), also yields (*A*) on sapon. (*A*) when submitted to the Friedel-Crafts reaction with PhH and AlCl₃ yielded *dl*-phenyl-*p*-tolylacetophenone, C₇H₇CHPhBz (*E*), hexagonal plates from light petr., m. 159-60°, and an unidentified compound b₁₂ 120°, m. 28-9°. Under similar conditions (*B*) also yielded (*E*). The above expts. indicate that (*B*) and (*C*) are much more readily racemized than is the corresponding PhCH(OH)CO₂H under similar conditions. M. and W. give a critical review of the literature dealing with desmotropic changes during racemization and conclude that the occurrence of desmotropism appears to be the most satisfactory interpretation of racemization of active compds. under the influence of alkali. The mechanism of the reactions involved in the racemization of (*B*) or (*C*) may be represented by some such scheme as the following:

$$\begin{array}{ccccc}
 \text{C}_7\text{H}_7\text{CHPhCO}_2\text{H} & \longrightarrow & \text{C}_7\text{H}_7\text{CHPhC.OH} & \longrightarrow & \text{C}_7\text{H}_7\text{CPh:C.OH} \\
 \text{(active)} & & \text{(active)} & & \text{(inactive)} \\
 & & \begin{array}{c} \parallel \\ \text{O} \\ \diagup \quad \diagdown \\ \text{K} \quad \text{OH} \end{array} & & \begin{array}{c} \diagup \quad \diagdown \\ \text{O}-\text{H} \\ \text{K} \quad \text{OH} \end{array}
 \end{array}$$

→ C₇H₇CHPhCO₂K + H₂O, emphasizing that addition precedes desmotropism.

LOUIS E. WISE.

Constitution of carbamides. II. Relation of cyanamide to urea. Constitution of cyanamide and the mechanism of its polymerization. EMIL A. WERNER. Trinity Coll., Dublin. *J. Chem. Soc.* 107, 715-28(1915); cf. *C. A.* 8, 2342.—Although a number of expts. dealing with the mechanism of polymerization of cyanamide (*A*) have been published (cf. Grube and Krüger, *C. A.* 8, 876; Morrell and Burgen, *C. A.* 8, 2590), the primary question of the constitution of (*A*) has not been discussed and the structural formula NCNH_2 has been considered to represent all of the properties of (*A*). In pure, neutral solns. of (*A*), which are exceedingly stable, W. assumes the existence of an electrostatic equil. which may be represented by the scheme: $\text{C}(\text{:NH})_2$ (*a*) $\rightleftharpoons$ NCNH_2 (*b*).
(acidic form) (basic form)

The addition of either an acid or a base to this neutral soln. will disturb the equil. and polymerization will begin as the result of an effort to maintain equil., *e. g.*, the addition of a strong acid will neutralize the *basic form* (*b*), causing the conversion of (*a*) into (*b*) and polymerization with the formation of dicyanodiamide (*B*), $\text{H}_2\text{NC:N.C}(\text{NH}_2)\text{:N}$

(Hoffman's formula). On the other hand, if a base is added to the soln. of (*A*), (*b*) passes into (*a*) which is polymerized with the formation of (*B*), $\text{HN:C.NH.C}(\text{:NH})\text{:NH}$

(Baumann's formula). G. and K.'s ionic theory, which throws little light upon the mechanism of polymerization, is unsound since polymerization of (*A*) has been shown to take place in non-ionizing solvents, such as dry Et_2O . W.'s equil. theory, however, is in complete agreement with all facts observed by G. and K. and by M. and B. Although (*A*) furnishes a neutral soln., its acidic character, as far as the production of metallic derivs. is concerned, is more pronounced than are its basic properties. W. shows experimentally that a weak base like NH_4OH has a greater disturbing effect on the equil. (*a*) $\rightleftharpoons$ (*b*) and therefore a greater accelerating influence on polymerization than a correspondingly weak acid like AcOH . Even traces of alkali extd. from glass vessels cause decided polymerization. The polymerization of (*A*) by heat alone is also satisfactorily explained by W.'s hypothesis. (*A*) and HNO_2 (liberated by the action of AcOH on NaNO_2) showed no signs of interaction even after an hr., a result which could not be expected, provided (*A*) were wholly present in the (*b*) form. In the presence of H_2SO_4 , (*A*) reacted instantaneously with HNO_3 with the evolution of N, the vol. of which after 2 min. amounted to 50% of the theoretical vol. demanded by the equation $\text{NCNH}_2 + \text{ONOH} \rightarrow \text{N}_2 + \text{H}_2\text{O} + \text{NCOH}$. This reaction was followed by a very slow continuous evolution of gas composed largely of CO_2 and due mainly to the gradual hydrolysis of NCOH . After an hr. over 0.5 of (*A*) was still unchanged and much free HNO_3 was present. Even when the reaction was allowed to continue for 20 hrs. nearly 13% of (*A*) still remained undecompd. These results are in harmony with W.'s equil. theory. Apparently (*b*) is rapidly decompd. at the outset by HNO_3 and (*a*) passes gradually into (*b*) in an effort to maintain the equil. The expts. show that in a normal soln. of (*A*), the equil. mixt. contains about 60% (*a*) and 40% (*b*). W. shows experimentally that the general impression that (*A*) is readily hydrolyzed with the formation of urea is erroneous. Even on heating in a sealed tube with H_2O alone for several hrs. at $120-30^\circ$, (*A*) yielded no urea, in fact the production of urea in the free state from (*A*) was never accomplished. Baumann's expts. (*Ber.* 6, 1373) in which urea nitrate was formed from (*A*) in moist Et_2O by means of HNO_3 (d. 1.42) were repeated and studied quant. W. shows that the amt. of urea nitrate formed is detd. by the quantity of HNO_3 present. When insufficient HNO_3 was added to completely convert (*A*), the residual (*A*) remained unpolymersed in soln., since the NHO_2 was always quant. removed by the urea formed. Provided sufficient H_2O was originally present in the (*A*) soln. to theoretically bring about complete dissociation of the urea nitrate if formed, no urea was generated, and the presence of HNO_3 only caused the gradual polymerization of (*A*).

These results are in harmony with the contention that urea in the static condition has the structure $\text{HN}:\text{C}(\text{NH}_2)_2$. The older view that (A) is the nitrile of urea renders the

exptl. facts unintelligible. The reaction between (A) and HNO_3 may be represented by the following equation: $\text{NCNH}_2 + \text{H}^+ + \text{OH}^- + \text{HNO}_3 \longrightarrow \text{HOC}(\text{:NH})\text{NH}_2 \cdot \text{HNO}_3$.

(isocarbamide form)

The isocarbamide structure is apparently only retained in the salt form, in the presence of little H_2O .

LOUIS E. WISE.

Steric influence, static and dynamic. II. OLIVER C. M. DAVIS AND FREDERIC W. RIXON. Bristol Univ. *J. Chem. Soc.* 107, 728-36(1915).—The interaction between HCO_2H and PhNH_2 and other aromatic amines leading to the formation of anilide was studied. The following were the parent amines used: *o*-, *m*- and *p*-methyl-, methoxy-, chloro-, and -bromoanilines, and α - and β - $\text{C}_{10}\text{H}_7\text{NH}_2$. The velocities of formation and of decompn. of the anilides and the position of equil. obtained by a direct method were detd. with a view of comparing their relative values as applied to steric hindrance. In detg. rates of formation 1 g. mol. per l. of PhNH_2 (or its congeners, RNH_2) was weighed into a measuring flask, a weighed amt. of standardized HCO_2H (1.1 g. mol. per l.) in $\text{C}_6\text{H}_5\text{N}-\text{H}_2\text{O}$ soln. (2 vols. $\text{C}_6\text{H}_5\text{N}$ and 1 vol. H_2O) was added, and the required vol. made up with $\text{C}_6\text{H}_5\text{N}-\text{H}_2\text{O}$. An aliquot portion was immediately weighed and titrated with 0.1 *N* NaOH, and 6 other portions were placed in previously steamed Jena glass tubes, which were loosely stoppered and heated in a H_2O bath. At intervals of 15 min. a tube was removed, rapidly cooled and its weighed contents titrated. The following formula was used in the calcn. of the const.: $k = [1.4/t(b-a)(b-x)] \log [a(b-x)/b(a-x)]$, where t = time in min., a = concn. of $\text{RNH}_2 = 1$, b = concn. of $\text{HCO}_2\text{H} = 1.1$ and x = amt. of anilide formed. In detg. the rate of decompn. a soln. of the following compn. was used: PhNHCHO (or other anilide RNHCHO), 1 g.-mol. per l.; HCO_2H , 0.1 g.-mol. per l.; H_2O , 1 g.-mol. per l. (in addition to the H_2O present in the $\text{C}_6\text{H}_5\text{N}-\text{H}_2\text{O}$ solvent). After a portion of the soln. had been titrated, the remainder was heated in a Jena flask fitted with a ground glass reflux condenser. Portions of the soln. were removed by pipet every hour, cooled, weighed and titrated. The formula used in computing the const. was: $k_2 = [1/t(a-b)] \log [a(b+x)/b(a-x)]$, where a = concn. of anilide or $\text{RNHCHO} = 1$, b = concn. of $\text{HCO}_2\text{H} = 0.1$, x = amt. of anilide formed in t min. The equil. method has been previously described (cf. Davis, *C. A.* 6, 567), the formula in this case being $K_w = a/(b+c)$, where a , b and c are the concns. of RNHCHO , RNH_2 and HCO_2H , resp. Tabulated data of av. values for k , k_2 and k_w and k_1/k_2 are given, together with max. differences of any const. from the average (in the case of k_1 and k_2) and the % anilide present in soln. at the equil. pt. A comparative table is also given in which the values k_1 and k_2 for PhNHCHO and the % PhNHCHO formed are taken as unity and the proportional values for the congeners, RNHCHO , are computed. From this the effects of different substituted groups and of the positions of a single substituent may be directly compared. Rates of formation and % RNHCO formed run approx. parallel, the values in the case of *o*-, *m*- and *p*-isomers increasing in the order mentioned. No regularity was noted in the rates of decompn. The effects of various groups substituted in similar positions may be listed in the following order of influence: (*o*-position) β -ring > OMe > Me > α -ring > Br > Cl ; (*m*-position) Me > Cl > (?) Br ; (*p*-position) OMe > Me > Cl > (?) Br . Very slight differences in the numbers for Br and Cl make the order of influence questionable; in fact the similar results obtained in the case of the halogens point to the conclusion that the greater wt. of Br is counterbalanced by the chem. activity of Cl . R. also gives a table of factors (for substituted groups and positions), which have been compounded of the steric influence and the chem. effect of the substituents.

LOUIS E. WISE.

Synthesis of α -naphthapyranols. BROJENDRA N. GHOSH. Univ. Coll., London. *J. Chem. Soc.* 107, 739-44(1915).—2-Methyl-4-methylene-1,4- α -naphthapyranol (A),

, pale, buff-colored needles with 0.5 H₂O from acetone, m.

166° (decompn.), was formed by heating a mixt. of 7 g. α -C₁₀H₇OH, 5 g. Ac₂CH₃ and 2-3 cc. POCl₃ for 0.25 hr. at 100-5°, dissolving the product in EtOH and treating the soln. with an excess of aq. AcONa. In concd. H₂SO₄, (A) dissolves with a brown color, and develops a green fluorescence. The following derivs. of (A) were prepd.: *Picrate*, yellowish green needles, m. 159° (decompn.); *chloromercurate*, yellowish brown; *perchlorate* (2 H₂O), explodes on heating; *chloroplatinate*, (2 H₂O), yellow crystals; *chloroaurate* (3 H₂O), brown microcrystals; *hydrochloride* (1 H₂O), yellow crystals, decomp. 96°. By substituting BzCH₂Ac for Ac₂CH₃ in the above reaction, G. prepd. 2-phenyl-4-methylene-1,4- α -naphthapyranol (1 H₂O), m. 125° (decompn.); *picrate*, yellowish green needles, m. 165°; *chloromercurate*, brown, amorphous; *perchlorate* (1 H₂O), green needles deflagrating with explosive violence; *chloroplatinate*, brown needles. L. E. W.

Syntheses with the aid of monochloromethyl ether. III. Action of monochloromethyl ether on sodium derivatives of ethyl ethane- α,β,β -tricarboxylate, ethyl butane- $\alpha,\alpha,\delta,\delta$ -tetracarboxylate and ethyl pentane- $\alpha,\alpha,\epsilon,\epsilon$ -tetracarboxylate. JOHN L. SIMONSEN. Presidency Coll., Madras. *J. Chem. Soc.* 107, 783-92(1915).—Ethyl γ -methoxypropane- α,β,β -tricarboxylate (A), MeOCH₂C(CO₂Et)₂CH₂CO₂Et, b₇ 161°, was formed by condensing EtO₂CCH₂CNa(CO₂Et)₂ with MeOCH₂Cl in PhH. When heated under reflux on a sandbath for 5 hrs. with 50% HCl, (A) was converted into itaconic acid, m. 161-2°. When heated with alc. KOH for 1 hr., (A) formed a gelatinous *potassium γ -methoxypropane- α,β,β -tricarboxylate*, which readily yielded the corresponding *free acid* (B), chalky crusts of microneedles from PhH-Et₂O, decomp. 145-5°; *silver salt*, flocculent ppt. When heated to 150°, (B) loses CO₂, giving rise to *γ -methoxypropane- α,β -dicarboxylic acid* (C), needles, m. 102° (*silver salt*, microscopic plates), identified by its conversion into CH₂ICH(CO₂H)CH₂CO₂H, m. 139-40° (cf. Swarts, *Jahresb.* 1866, 722, who gives 135°) and CH₂BrCH(CO₂H)CH₂CO₂H (D), m. 137° (cf. Beer, *Ann.* 216, 79). On distn. (C) yielded citraconic anhydride, b₇₄₄ 215-7° (Anschütz, *Ber.* 13, 1542, gives 213-4°). AcCl reacting with (C) at 150-60° gave rise to CH₂ClCH(CO₂H)CH₂CO₂H, m. 140-1°. When heated with alc. KOH (D) formed mesaconic acid, m. 199°, apparently the sole reaction product. By a reaction analogous to that used in the synthesis of (A), using [CH₂CH(CO₂Et)₂]₂ (E), instead of CH₂(CO₂Et)CH(CO₂Et)₂, S. obtained an inseparable mixt. of (E) and *ethyl α,δ -dimethoxyhexane- $\beta,\beta,\epsilon,\epsilon$ -tetracarboxylate* (F) which even after repeated distn. b₁₃ 225°, together with only a small amt. of pure (F), prisms from alc., m. 92-3°. (F), when boiled with concd. HCl, yielded $\Delta^{\alpha,\epsilon}$ -hexadiene- β,ϵ -dicarboxylic acid (G), [CH₂:C(CO₂H).CH₂]₂, woolly needles, m. 180-1°, *silver salt*, caseous ppt. The mixt. of (E) and (F), b₁₃ 225°, when subjected to hydrolysis yielded what was probably a eutectic mixt. of [(G) and adipic acid], needles, m. 112°, even after repeated recrystn., rather than the expected pentenedicarboxylic acid, C₇H₁₀O₄, since on oxidation with KMnO₄, followed by CrO₃, it yielded a mixt. of adipic acid and (CH₂CO₂H)₂ and when reduced with H in the presence of Pd formed only adipic acid. Condensation of [(EtO₂C).CHCH₂]₂CH₂ (H) with MeOCH₂Cl in the presence of Na gave rise to a similar mixt. of [(H) and *ethyl β -methoxyhexane- $\alpha,\alpha,\epsilon,\epsilon$ -tetracarboxylate*], b₆ 220-2°, which on hydrolysis with HCl yielded pimelic acid and Δ^{α} -hexene- β,δ -dicarboxylic acid, CH₂:C(CO₂H)CH₂(CH₂)₂CH₂CO₂H, platelets (from Et₂O-petroleum), m. 77-9°. The latter on oxidation with KMnO₄ yielded adipic acid. LOUIS E. WISE.

Condensation of ethyl cyanoacetate and acetylacetone. JOHN L. SIMONSEN AND MUDLAGIRI NAYAK. Presidency Coll., Madras. *J. Chem. Soc.* 107, 792-8 (1915).—The research was undertaken with the object of obtaining an allene deriv. of the type $RMeC:C(CMeR)$ (where $R = [CH(CN)CO_2Et]$) by the interaction of $NCCH_2CO_2Et$ and Ac_2CH_2 in the presence of Et_3NH . The principal condensation product, however, proved to be $MeC:C(CO_2Et).CO.NH.CMe:CH$ (A), needles, m. $135-6^\circ$ (cf. Knoe-

venagel and Cremer, *Ber.* 35, 2393), which on hydrolysis with KOH yielded the corresponding free acid (B), needles, decomp. 247° (K. and C. give 254°). When hydrolyzed with HCl (A) gave rise to ψ -lutedocarbostyryl hydrochloride $C_7H_9ON.HCl.H_2O$ (C), prisms, m. 127° (cf. Hantzsch, *Ber.* 17, 2904, who describes a similar compd. containing 2 H_2O). The free base formed by shaking (C) with Ag_2O , m. 180° ; its *picrate*, yellow prisms, m. $155-6^\circ$. Bromination of (A) in $CHCl_3$ gave rise to *ethyl 5-bromo-4,6-dimethyl-2-pyridone-3-carboxylate*, silky needles, m. 199° , readily converted into the corresponding *free acid*, leaflets, m. $255-6^\circ$, also formed by direct bromination of (B) in $AcOH$. Methylation of (A) followed by hydrolysis of the resulting Et-Me ester mixt. yielded *1,4,6-trimethyl-2-pyridone-3-carboxylic acid*, iridescent needles from alc., m. 210° , forming a sparingly sol. *copper salt*, pale blue needles, and an insol. *lead salt*, prisms, yielding no MeI when heated with HI in the Zeisel app. and forming $MeC:CH.CO.NMe.CMe:CH$

when heated at 270° . A small amt. of by-product obtained in the synthesis of (A) and isolated from the mother liquors, a *compound*, $C_{12}H_{14}O_2N_2$ (D), needles from alc., m. $190-1^\circ$, was possibly *ethyl α,ϵ -dicyano- β,δ -dimethyl- $\Delta^{6,8}$ -hexadienoate*, $NC.CH:-CMeCH:CMeCH(CN)CO_2Et$. A *monobromo derivative* of (D), $C_{12}H_{13}O_2N_2Br$, yellow needles, m. 196° . On sapon. with KOH (D) evolves NH_3 and apparently undergoes complete disintegration, since no other products except a trace of oil could be isolated.

LOUIS E. WISE.

Resolution of externally compensated *p*-toluenesulfonylalanine into its optically active components. CHARLES S. GIBSON AND JOHN L. SIMONSEN. Maha Rajah's Coll., Travancore, and Presidency Coll., Madras. *J. Chem. Soc.* 107, 798-803 (1915).—*dl*-4- $MeC_6H_4SO_2NHCHMeCO_2H$ (cf. Pope and G., *C. A.* 7, 66) was resolved by treating 2 mols. of the acid in 1 mol. of N NaOH with 1 mol. brucine, sepg. *brucine l-p-toluenesulfonylalanine* (A), brittle plates, with 3 H_2O , m. $148-9^\circ$, $[M]_{546}^{29-30} -266.2^\circ$, pptg. the crude *d*-acid from the mother liquor by means of HCl and purifying it by conversion into the *strychnine d,p-toluenesulfonylalanine* (B), prisms with 2 H_2O from H_2O , m. $188-9^\circ$, $[M]_{546}^{29-30} -68.7^\circ$. The order of removal of active components may be advantageously reversed, (B) being first formed and removed from soln. prior to the formation of (A). On acidification (A) yields the free *l*-acid, needles from aq. alc., m. $131-2^\circ$, $[M]_{546}^{29-30}$ (0.202 g. of Na salt in 30 cc. of aq. soln.) -82.1° , optical activity increasing markedly with increase in conc. Similarly (B) yields the free *d*-acid, long needles, m. $131-2^\circ$; $[M]_{546}^{29-30}$ 81.7° (0.202 g. of Na salt in 30 cc. of aq. soln.).

LOUIS E. WISE.

Condensation of acid chlorides with the ethyl ester of (a) cyanoacetic acid, (b) malonic acid, and (c) acetoacetic acid. II. Experiments on ethyl γ -ethoxyacetoacetate. JOHN BRADSHAW, HENRY STEPHEN AND CHARLES WEIZMANN. Manchester. *J. Chem. Soc.* 107, 803-13 (1915); cf. *C. A.* 8, 904.— $NaCH(CO_2Et)_2$ reacting with $o-C_6H_4(CO)_2NHCH_2COCl$ gave rise to *ethyl bisphthaliminoacetylmalonate* (A), $[o-C_6H_4(CO)_2NCH_2CO]_2C(CO_2Et)_2$, needles, m. 176° . *1-Phenyl-3-phthaliminomethyl-5-pyrazolone*, $o-C_6H_4(CO)_2NCH_2C:N.NPh.CO.CH_3$, microcrystals, m. 192° (decompn.), prepd. from $PhNHNH_2$ and Et phthaliminoacetoacetate, when hydrolyzed with alc. KOH yielded *1-phenyl-3-phthalaminomethyl-5-pyrazolone* (B), yellow powder,

m. 164° (decompn.). Et phthaliminoacetylmalonate (C) and PhNHNH_2 condensed to form *ethyl 1-phenyl-3-phthaliminomethyl-5-pyrazolone-4-carboxylate* (D), $\text{o-C}_6\text{H}_4(\text{CO})_2\text{NHCH}_2\text{C:N.NPh.CO.CHCO}_2\text{Et}$, yellow powder, m. 215° , from which the

corresponding (impure) phthalimino deriv. was obtained. On fusion, the latter evolved CO_2 and yielded (B). By warming an excess of PhNHNH_2 with (A) in 50% AcOH , a mixt. of (D) and *phthaliminoacetylphenylhydrazide* (E), $\text{o-C}_6\text{H}_4(\text{CO})_2\text{NCH}_2\text{CONHNHPh}$, needles from MeOH , m. 199° , was obtained. (E) was readily formed by condensing $\text{o-C}_6\text{H}_4(\text{CO})_2\text{NCH}_2\text{COCl}$ with PhNHNH_2 . By treating (C) in KOH with NaNO_2 and subsequently adding dil. H_2SO_4 , α -hydroxyimino- γ -phthaliminoacelone, $\text{o-C}_6\text{H}_4(\text{CO})_2\text{NCH}_2\text{CO.CH:NOH}$, prisms from PhH , m. 156° (decompn.), was obtained. When Et_2NH was gradually added to an ice-cold mixt. of 2 mols. $\text{EtOCH}_2\text{COCH}_2\text{CO}_2\text{Et}$ and 1 mol. AcH , *ethyl ethylidenebis- γ -ethoxyacetoacetate*, needles (from MeOH), m. 96° , was formed, which when heated for 20 hrs. with aq. H_2SO_4 , or preferably when dissolved in an equal vol. of PhH and satd. with HCl , yielded *1-ethoxy-4-methyl-2-ethoxymethylcyclohexen-6-one*, b_{18} 157° , possessing a terpene-like odor; *semicarbazone*, plates, m. 232° (decompn.). $\text{EtOCH}_2\text{COCHMeCO}_2\text{Et}$ (F), b_{18} 115° , and $\text{EtOCH}_2\text{COCHEtCO}_2\text{Et}$ (G), b_{18} 124° (cf. Johnson, *J. Chem. Soc.* 35, 582), were formed by treating 1 mol. $\text{EtOCH}_2\text{COCHNaCO}_2\text{Et}$ in EtOH with 1 mol. of MeI and EtI , resp. Similar reactions led to the formation of *ethyl γ -ethoxy- α -propylacetoacetate*, b_{18} 137° ; the corresponding α -isopropylacetoacetate, b_{18} 131° , and α -isobutylacetoacetate, b_{18} 128° , $\text{MeCH}_2\text{COCH}_2\text{OEt}$, b. 146° , and $\text{EtCH}_2\text{COCH}_2\text{OEt}$, b. 167° (cf. Béhal and Sommelet, *Compt. rend.* 138, 89), were obtained in poor yield from (F) and (G), resp., by heating the esters with H_2O in sealed tubes at 210° for 1 hr. The other alkylacetoacetates were hydrolyzed in the same way, "acid hydrolysis" being the principal reaction as shown by the titration of the acid formed during the reaction. $\text{EtOCH}_2\text{COCl}$ and NH_3 in dry Et_2O yielded $\text{EtOCH}_2\text{CONH}_2$, needles from PhH , m. $80-2^{\circ}$ (cf. Sommelet, *Ann. chim. phys.* [8] 9, 493). One mol. of $\text{EtOCH}_2\text{COCH:NOH}$ reacting with 1 mol. of $\text{o-C}_6\text{H}_4(\text{NH}_2)_2$ in 2 mols. of glacial AcOH gave rise to *2-ethoxymethylquinoxaline* (H), $\text{CH:N.C}_6\text{H}_4\text{N:CCH}_2\text{OEt}$, b_{18} 144° , neutral to litmus in aq. soln.; *chloro-*

platinate, microcrystals, decomp. 250° ; *picrate*, yellow powder, m. 216° . Upon gradual oxidation with alk. KMnO_4 , (A) yielded *pyrasine-2,5,6-tricarboxylic acid*, $\text{HO}_2\text{CC:C(CO}_2\text{H).N:CH.C(CO}_2\text{H):N}$, silky needles, m. 191° (decompn.), isolated

as the barium salt. The normal copper salt forms green microcrystals from aq. MeOH .

LOUIS E. WISE.

Rotation of isobutyl diacetyl-d-tartrate. THOMAS S. PATTERSON AND DONALD N. MCARTHUR. *J. Chem. Soc.* 107, 814-5 (1915).—The $[\alpha]_D$ and d. of *isobutyl diacetyl-d-tartrate* (A), b_{11} 183° , prepd. from *iso-Bu d-tartrate* and AcCl , were detd. at temps. ranging from 15.3° to 179° and the $[M]_D$ calcd. The following are the values of $[M]_D$, the temps. being given in parentheses: (15.3°) 55.01; (36.8°) 52.66; (65.5°) 51.59; (80.3°) 51.77; (93.6°) 52.17; (103.3°) 52.89; (131°) 55.34; (144.5°) 56.09; (160°) 57.54; (179°) 60.61. The $[M]_D$ of (A) in PhNO_2 ($p = 9.6\%$) were as follows: (-4.2°) -5.88 ; ($+0.8^{\circ}$) -4.73° ; (18.3°) -1.2 ; (36.2°) 3.24 ; (54.6°) 7.83 ; (80.1°) 14.3 ; (93.2°) 16.61 ; (110°) 22.04 ; (117.5°) 23.93 ; (125°) 25.8 ; (141°) 30.21 . The rotation of (A) closely resembles those of Et and *iso-Bu* ditrichloroacetyl tartrate (cf. *C. A.* 6, 2064; 7, 3705).

LOUIS E. WISE.

Nitration of 3-acetyl-amino-2-methoxytoluene. JOHN L. SIMONSEN AND MUDLAGIRI NAYAK. Presidency Coll., Madras. *J. Chem. Soc.* 107, 828-34 (1915).—3-Acetyl-amino-2-methoxytoluene (37 g.), needles, m. $100-1^{\circ}$, when gradually added to ice-cold fuming HNO_3 , yielded 48 g. of mixed NO_2 derivs. which were sep'd. as follows:

Monatsh. **25**, 475, 1177, etc.) and of other investigators. In the prepn. of *di-o-xylylphthalide*, $(3,4\text{-Me}_2\text{C}_6\text{H}_3)_2\text{C}_6\text{H}_4\text{CO}_2\text{O}$, powder, m. $107\text{--}8^\circ$, the by-product was *o*-

xylylphthalolylic acid, prisms, m. $161\text{--}2^\circ$ (cf. M.). *Di-1-ethoxynaphthylphthalide* (A), β -(α -EtOC₁₀H₇)₂C₆H₄CO₂O, m. 159° . The by-product, *o*-1-ethoxynaphthyl-

benzoic acid, HO₂CC₆H₄COC₁₀H₆OEt, plates from EtOH, m. $155\text{--}6^\circ$, forming an ammonium salt, plates, and yielding *o*-HO₂CC₆H₄COC₁₀H₆OH, m. $185\text{--}6^\circ$, when heated with AlCl₃ in CS₂ (cf. Deichler and W., *Ber.* **36**, 556). Similarly by the displacement of Et groups in (A) by H, α -naphthaphthalein, brownish yellow crystals, m. $209\text{--}10^\circ$, was formed (cf. Grabowski, *Ber.* **4**, 725), which on heating at 290° passed into α -naphthafuorane, m. 300° (also prepd. by G.). [In the formulas of the following compds,

the substituent groups are in positions 3 and 6.] 9-Ethylcarbazole, on treatment with phthalyl chloride and AlCl₃, yielded as the minor reaction products *9-ethylcarbazole-3-phthaloylic acid*, HRCOC₆H₄CO₂H, needles, m. $188\text{--}9^\circ$, sol. in PhH, and *9-ethylcarbazole-3,6-diphthaloylic acid* (B), R(COC₆H₄CO₂H)₂, rhombs, m. $266\text{--}8^\circ$, insol. in PhH; the silver salts of both acids were white ppts., stable to light. The main products of the above reaction were *di-9-ethylcarbasyphthalide*, (HR)₂C₆H₄CO₂O, yellow, sol. in EtOH, decomp. above 155° , a *tri-9-ethylcarbasyldiphthalide*, O.CO.C₆H₄C(RH).R.C(RH).C₆H₄CO₂O, pale yellow, decomp. above

235° , insol. in EtOH. When heated with 25 parts of H₂SO₄ for 5 hrs. at 99° , (B) yielded 2,3,6,7-diphthaloyl-9-ethylcarbazole, C₆H₄(CO)₂C₆H₂—C₆H₂(CO)₂C₆H₄,

monoclinic needles, does not m. below 300° . The phthalides all give marked colorations when treated with concd. H₂SO₄.

LOUIS E. WISE.

Walden inversion. II. Kinetics and dissociation constant of phenylchloroacetic acid. G. SENTER. *J. Chem. Soc.* **107**, 908-15(1915); cf. C. A. **9**, 2227.—The mechanism of hydrolysis of PhCHClCO₂H to PhCH(OH)CO₂H was studied with the view of detg. whether the ionized or un-ionized portion of the acid is the main factor in the reaction. The dissociation const. K of PhCHClCO₂H at 25° was found to be 0.0046 (Λ_∞ for PhCHClCO₂H = 377). S. finds that in contrast to CH₂ClCO₂H, the rate of hydrolysis of non-ionized PhCHClCO₂H is negligible when compared with that of the PhCHClCO₂⁻ ion. This was shown by a quant. study of the retarding action of HCl upon PhCHClCO₂H hydrolysis since HCl diminishes the PhCHClCO₂⁻ concn. The mechanism of the reaction was further detd. by means of expt. which no HCl was initially added, using the method of formulation (for "analysis") proposed by S. and Porter (C. A. **5**, 3053) in which all mathematical assumptions were justified by the initial assumption that only the anion PhCHClCO₂⁻ goes on hydrolysis. In the case of PhCHClCO₂Na, similar results were obtained, the anion undergoing hydrolysis. The temp. coeff. for 1 M. PhCHClCO₂Na has a slight accelerating influence upon the reaction, the activation energy which tends to disprove the suggestion of V.

are in equil. with a certain amount of the hydrolysis of PhCH(OH)COOH is the same as in the case of 0.1 N and 0.5 N NaOH solutions, that the effect of the OH^- ion in the main reaction in the hydrolysis of PhCH(OH)COOH is in each case the same, $\text{PhCH(OH)COOH} + \text{H}_2\text{O} \rightarrow \text{PhCH(OH)COO}^- + \text{H}^+$ the adequacy of the orthodox mechanism involved in the Walden inversion.

Glucosidification of glycerol

QUELOT, M. BRIDEL AND A. BRIDEL. Each containing 150 g. glucose. The mixture at lab. temp. for about 8 months. Five g. of emulsin were then added. The mixture showed $[\alpha]_D^{20} -0.20'$. The mixture after 0.5 hr., cooled, treated with 5 g. of yeast added to destroy unchanged glucose. The mixture heated to boiling, refiltered and the residue was extd. with a mixt. of CH_2Cl_2 and CHCl_3 . The residue after removal of glycerol and repptg. by means of 500 cc. of EtOH and 200 cc. of boiling EtOH , reprecipitated was obtained. The amorphous residue on hydrolysis with dil. H_2SO_4 gave a monoglyceryl glucoside, but from the study by detg. the α and the β anomers believe that (A) is a mixt. of at least two in their resistance towards the hydrolysis.

Ketodilactone of benzophenone

Jesus Coll. Proc. Cambridge Phil. Soc. with 9% HNO_3 for 70 hrs. is converted to phenonedicarboxylic acids predominately. KMnO_4 gives an excellent yield of benzophenone on warming with strong HCl for a few minutes. $\text{O.O.C.C}_6\text{H}_4(\text{CO.H})\text{C.C.H}_3$ is the dilactone.

to give deriv

of *d*-ethylisopropylmalonic monoamide into *inactive* ethylisopropylmalonic acid by the action of HNO_2 (cf. *C. A.* 8, 1102) is proof of the equivalence of the bonds holding the 2 CO_2H groups, while the conversion of *d*-allylpropylcyanoacetic acid (a) into *inactive* dipropylcyanoacetic acid (b) proves the equivalence of the bonds to the alkyl rests. The proof that the members of one pair are equal to those of the other, i. e., that the bond of an alkyl and that of a CO_2H are of equal value, remains for a future investigation. $\text{PrCH}(\text{CN})\text{CO}_2\text{Et}$ (c), previously prepd. by Henry (cf. *Jahresber.* 1889, 638), was a mixt. of the mono- and di-Pr esters. These may be sepd. by sapon. of the crude mixt. with 2.0 *N* NaOH at room temp., which leaves the di-Pr ester unaltered. Propylcyanoacetic acid (d), $b_{0.2}$ 125–30°, forms a silver salt from which (c) may be prepd. pure by the action of EtI . (c) b_{16} 105–10°, b_{716} 222–3°. (b) $b_{0.2}$ 135–40°; d_4^{18} 0.988; dissolved in hot H_2O , it seps. as an oil which slowly forms a *monohydrate*, rhombic or hexagonal tables which shrivel at 45° and m. 49–50°; dried under 0.5 mm. at 36° over P_2O_5 , it forms a hard cryst. mass, m. 33–4°; the ammonium salt and silver salt are both cryst. *dl*-Allylpropylcyanoacetic acid (f), obtained by sapon. of the Et ester with alc. KOH for 4 hrs., $b_{0.16}$ 129–30, d_4^{18} 1.102 and crystals in needles on long standing, m. 25–35°; yield 74%. Lead, ammonium and silver salts all sep. in needles; (f) gives a cryst. ppt. with CaCl_2 , a reddish brown soln. with FeCl_3 and decolorizes KMnO_4 . Ethyl ester, from (c), Na and $\text{C}_3\text{H}_5\text{I}$, b_{16-20} 125–30°, b_{716} 241–2°; yield 83%. (f) is split into its optical components by conversion into its *brucine* salt, the salt of the *d*-form (a) sepg. first in needles. This was purified through the *morphine* salt, stout prisms containing H_2O . (a) seps. from Et_2O in microscopic needles or prisms, m. 42°, and sublimates slowly even at 36°; $[\alpha]_D^{18}$ in *N* NaOH 16.74°; $[\alpha]_D^{25}$ in neutral soln. 18.47°; $[\alpha]_D^{22}$ in glacial AcOH 7.97°. *l*-Allylpropylcyanoacetic acid seps. as the *brucine* salt in large tables from the mother liquor from (a). Reduced with Pt black in glacial AcOH or in alk. soln. (a) is converted into (b). 20.0 g. (f) heated with 100 cc. concd. H_2SO_4 for 4 hrs. gives the propyloxypropylmalonic monoamide lactone, $\text{C}_3\text{H}_7\text{C}(\text{CONH}_2)\text{C}_3\text{H}_5\text{OC}_2\text{O}$, 6-sided plates from H_2O , m. 96–7°. The H_2O soln.

is weakly acid to litmus and when warmed with alkali evolves NH_3 ; when the alk. soln. is satd. cold with HCl , the propyloxypropylmalonic lactone seps. as an oil which was identified through its calcium salt, $(\text{C}_3\text{H}_{13}\text{O}_4)_2\text{Ca} \cdot 2\text{H}_2\text{O}$, tables. 5.0 g. (f) in Na_2CO_3 treated with 16 g. KMnO_4 in 400 cc. H_2O is converted into a dibasic acid which is probably α,α -propylcyanosuccinic acid, $\text{HO}_2\text{CCH}_2\text{C}(\text{CN})\text{PrCO}_2\text{H}$; purified by pptn. from Et_2O by petrol. ether, it m. 123° with effervescence to a clear oil; warmed with CaCl_2 , it seps. a calcium salt. When (a) is oxidized under the same conditions as (f) it gives a similar product m. 123° with effervescence, but which seps. in fine needles or prisms and is optically active, $[\alpha]_D^{19}$ –32.0. Its calcium salt is more sol. than that of the *dl*-form. The yields of both acids were small.

NORMAN A. SHEPARD.

Reaction of nopic acid (a reaction characteristic of oxalic acid). BERNABÉ DORRONSORO AND OBDULIO FERNÁNDEZ. *Anales soc. españ. fis. quim.* 11, 441–3 (1913).—D. and F. correct a misinterpretation of data in a previous paper (*Anales soc. españ. fis. quim.* 8, 323) in which a green coloration obtained with resorcinol (in H_2SO_4 soln.) was attributed to the presence of nopic acid. The product obtained by oxidizing the pinene of Spanish oil of turpentine with alk. (NaOH) KMnO_4 soln. was very slightly sol. in H_2O , decolorized KMnO_4 in slightly acid (H_2SO_4) soln. and decompd. PbO_2 ; this product was, therefore, supposed to be Na nopate. It was impossible, however, to sep. nopinone (by distn. with steam and formation of the semicarbazone) after oxidizing with acid KMnO_4 the salt obtained as above; the compd. which was supposed to be Na nopate gave a ppt. (sol. in dil. HCl) with CaCl_2 , while nopic acid gives (according to Baeyer) a very sol. Ca salt. The acid of the above salt was isolated

by treatment with dil. H_2SO_4 and extn. with Et_2O ; the m. p. was nearly that of pinonic acid, but identity with the latter was excluded because the ketone reaction was negative. Crystals, m. 90° , were obtained when the Ca salt (insol. in AcOH) was treated with H_2SO_4 and extd. with Et_2O ; the aq. soln. yielded crystals which showed the comp. $\text{H}_3\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$. Repeated expts. with samples of pinene of varying origin showed that the salt obtained by oxidation with alk. KMnO_4 is $(\text{CO}_2\text{Na})_2$. The previously described color reaction with resorcinol and H_2SO_4 is, therefore, characteristic of $(\text{CO}_2\text{H})_2$.

H. S. PAINE.

Oxidation of nopinene of Spanish oil of turpentine. ANTONIO MADINAVEITIA. *Anales soc. españ. fis. quim.* 12, 259-64(1914).—In view of the contradiction of the statements of Dorransoro and Fernández (cf. preceding abstr.) to the results of Baeyer and Wallach, M. has reinvestigated the subject in order to ascertain if the discrepancy might be due to difference in comp. between Spanish oil of turpentine and the French and American oils of turpentine examd. by W. The $155-6^\circ$ fraction from the distn. of Spanish oil of turpentine was oxidized according to the W. procedure; 1.3% Na nopate was obtained as compared with 2.5-5% obtained by W. from American and French oils of turpentine. This yield was increased somewhat and the operation facilitated by means of a slight modification of the W. method. The soln. obtained after oxidation was concd. to $1/6$ (instead of $1/3$) its original vol.; the crystd. mixt. of Na nopate and $(\text{CO}_2\text{Na})_2$, thus obtained was recrystd. from a little H_2O and the impure Na nopate was dissolved in 40 times its wt. of H_2O . The oxalate in this soln. was pptd. by CaCl_2 ; the filtrate was acidified and extd. with Et_2O and the residue from evapn. of the latter was crystd. from C_6H_6 as in the original method. The nopic acid thus obtained, when crystd. from cold C_6H_6 , formed beautiful crystals which effloresced at ordinary temp. with loss of C_6H_6 of crystn. The crystals m. $125-6^\circ$ after being dried over H_2SO_4 and were sol. in alkalis and very slightly sol. in H_2O ; Na nopate was pptd. when the Et_2O soln. was shaken with satd. NaHCO_3 . Nopic acid was not affected by KMnO_4 in neutral or alk. soln.; it was oxidized by KMnO_4 in acid soln. with formation of nopinone. CaCl_2 did not produce a ppt. with nopic acid in NH_4OH ; the Et_2O soln. was slightly *l*-rotatory. Nopic acid identical with that obtained by Baeyer and Wallach from other turpentines may, therefore, be obtained by oxidation of Spanish oil of turpentine.

H. S. PAINE.

Existence of nopinene in Spanish oils of turpentine. B. DORRANSORO AND O. FERNÁNDEZ. *Anales soc. españ. fis. quim.* 12, 424-6(1914).—D. and F. reply to the comments of Madinaveitia (cf. preceding abstr.) on a previous paper by them. Repetition of their previous expts. with observance of the technic indicated by M. failed to show the presence of nopic acid after oxidation of oil of turpentine with alk. KMnO_4 ; the sample of turpentine employed had a max. b. p. $154-5^\circ$ and rotatory power $+1^\circ$ (another sample was optically inactive) and was obtained from *Pinus halepensis* (grown in Andalucía near the sea). In connection with the above positive rotation it is recalled that nopinene is usually described as being *l*-rotatory and contributing to the *l*-rotation of turpentine; furthermore, the pinene which was not oxidized by alk. KMnO_4 showed practically the same rotation (after distn. with steam) as the original sample before oxidation.

H. S. PAINE.

A reaction of aldehydes with diphenylcarbazine. A new method for preparing substituted hydroxytriazoles. BERNARDO ODDO AND E. FERRARI. Univ. Pavia. *Gazz. chim. ital.* 45, I, 238-62(1915).—In the last ten years the use of $\text{CO}(\text{NHNHPh})_2$ (a) in volumetric analysis has been studied. The present paper is a first report on the condensation of (a) with $\text{C}:\text{O}$ compds. and deals with the aldehydes. Aldehydes easily condense in AcOH , in the presence of dry NaOAc , with (a) to give derivs. of

1-phenyl-1,2,4-triazolone (b), PhN.NH.CO.N:CR , or its tautomer *1-phenyl-3-hydroxy-1,2,4-triazole* (c), PhN.N:C(OH)N:CR . PhNH_2 is regularly formed as a by-product of

the reaction. The reaction may be formulated in 2 ways: (1) $(a) + \text{O:CHR} \longrightarrow \text{H}_2\text{O} + \text{PhNHN.CO.NH.NPh.CHR}$ and the latter gives $\text{PhNH}_2 + (b)$ or (c) ; (2) $(a) +$

$\text{O:CHR} \longrightarrow \text{PhNH}_2 + \text{O:CR.NH.CO.NH.NHPh}$ and the latter gives $\text{H}_2\text{O} + (b)$ or (c) . In (1) the pentaatomic nucleus is first formed and PhNH_2 is eliminated later through the lability of the methinic grouping: RCH-N-NHPh . In (2) PhNH_2 is first

eliminated and H_2O subsequently. Of these the first is considered most probable. PhNH_2 is only formed when aldehydes are used. With ketones a substituted aniline would have to be formed, so that the detection of PhNH_2 offers a delicate means of recognizing the aldehyde function of a compd. For this purpose O. and F. made special expts. to det. whether (a) treated alone under the conditions of the condensation does not give some PhNH_2 . On boiling (a) with glacial $\text{AcOH} + \text{NaOAc}$ only very small traces of PhNH_2 are formed. Even on distg. with steam PhNH_2 is only formed when the expts. are done in strongly alk. soln. which is not necessary for the distn. since PhNH_2 passes over in solns. acid with AcOH , neutral or faintly alk. The velocities of reaction of the various aldehydes are not equal. An OH or NO_2 in the *o*-position has a retarding effect. In the case of furfural and glucose the fact that the reaction takes place was detd. by the fact that PhNH_2 was detected, but the condensation product could not be isolated in the pure form. 2.4 g. (a) in 20 cc. glacial AcOH treated with the mol. amt. of NaOAc and heated under a reversed condenser 2 hrs. gave *1,5-diphenyl-3-hydroxy-1,2,4-triazole* (d), $\text{C}_{14}\text{H}_{11}\text{ON}_3$ (i. e., (c) in which $\text{R} = \text{Ph}$), white needles from AcOEt , m. 288° , sol. in dil. alks., does not react with Cu salts like (a), gives a colorless soln. in concd. HCl or H_2SO_4 , does not react with PhNHNH_2 , mol. wt. in AcOH $218 \pm$ (calcd. 237.11). The manner of its formation does not leave any doubt about its constitution. It gives an *acetyl derivative*, m. 133° , which on sapon. gives (d), m. 288° . The *hydrochloride* seps. from the HCl soln. as small needles that lose all HCl in the air gradually. The hydrochloride mother liquors give no turbidity with PtCl_4 but with $\text{HgI}_2\text{-KI}$ a white ppt., with phosphotungstic acid a white ppt., with $\text{BiI}_3\text{-KI}$ a brick-red ppt. and finally reduction, with phosphomolybdic acid a citron-yellow ppt., with Br_2 in KBr an orange ppt. and with AuCl_3 a yellow ppt. The *dihydrochloride*, $\text{C}_{14}\text{H}_{11}\text{ON}_3 \cdot 2\text{HCl}$, was obtained by passing HCl through (d) into Et_2O as a white cryst. powder, blackens near 200° , m. 288° . Similarly to (d) *5-p-tolyl-1-phenyl-3-hydroxy-1,2,4-triazole* was obtained from *p*- $\text{MeC}_6\text{H}_4\text{CHO}$ as white needles from AcOEt or EtOH , m. $275\text{--}6^\circ$, sol. in alks. and strong HCl . The *acetyl derivative*, $\text{C}_{15}\text{H}_{13}\text{N}_3\text{OAc}$, was obtained by boiling the compd. with $\text{Ac}_2\text{O} + \text{AcONa}$ for 8 hrs., minute needles, m. 107° ; sapond. it gives the parent compd., m. $275\text{--}6^\circ$. The *hydrochloride*, $\text{C}_{14}\text{H}_{13}\text{N}_3\text{O.HCl} \cdot 2\text{H}_2\text{O}$, seps. from concd. HCl as crystals, m. 275° ; *chloroaurate*, $\text{C}_{14}\text{H}_{13}\text{ON}_3 \cdot \text{HAuCl}_4 \cdot \text{H}_2\text{O}$, was pptd. as a yellow cryst. ppt., contracts 83° , m. 133° with previous softening. The hydrochloride gives a yellow-white ppt. with K_2CdI_4 , a white cheesy ppt. with $\text{HgI}_2\text{-KI}$ and a brick-red ppt. with $\text{BiI}_3\text{-KI}$. With salicylaldehyde (a) gave *5-o-hydroxyphenyl-1-phenyl-3-hydroxy-1,2,4-triazole*, needles from AcOEt , m. 297° (decompn.), little sol. in org. solvents, sol. in alkalies, gives a yellow ppt. with AuCl_3 , gives ppts. with the reagents for alkaloids. The *acetyl derivative*, $\text{C}_{15}\text{H}_9\text{O}_2\text{N}_3\text{Ac}$, was obtained as white needles from ligroin + C_6H_6 , m. 100° ; sapond. it gives the parent compd. *5-o-Methoxyphenyl-1-phenyl-3-hydroxy-1,2,4-triazole* was obtained similarly from *o*-anisaldehyde as needles from EtOH , m. 300° , sol. in alkalies, gives ppts. with the alkaloid reagents; *acetyl derivative*, $\text{C}_{15}\text{H}_{11}\text{O}_2\text{N}_3\text{Ac}$, prismatic needles from ligroin, m. 112° ; *hydrochloride*, $\text{C}_{14}\text{H}_{11}\text{-}$

$O_2N_1.HCl$, sepd. from Et_2O with HCl gas as needles. *5-o-Nitrophenyl-1-phenyl-3-hydroxy-1,2,4-triazole* was obtained similarly with $o-O_2NC_6H_4CHO$ as yellow prisms, m. $243-4^\circ$, gives a yellow soln. in alkalis and is repptd. with acids, gives ppts. with $AuCl_3$ and the alkaloid reagents; the *acetyl derivative* could not be crystd.; *hydrochloride*, prismatic needles. With $m-O_2NC_6H_4CHO$ *5-m-nitrophenyl-1-phenyl-3-hydroxy-1,2,4-triazole* was obtained as needles from C_6H_6 , m. $276-7^\circ$; *acetyl derivative*, m. 118° . With cinnamaldehyde *5- β -phenylethylphenyl-1-phenyl-3-hydroxy-1,2,4-triazole* was obtained as leaves, m. 286° ; *acetyl derivative*, $C_{18}H_{15}ON_3Ac$, prisms from ligroin. With piperonal *5-methylenedihydroxyphenyl-1-phenyl-3-hydroxy-1,2,4-triazole* was obtained as needles from $EtOH$, m. 274° ; *hydrochloride*, $C_{18}H_{15}O_2N_3.HCl$, aggregates of prisms from strong HCl , m. 274° ; *dihydrochloride*, $C_{18}H_{15}O_2N_3.2HCl$, sepd. from Et_2O with HCl gas as pale rose-colored needles, m. 274° ; the *acetyl derivative*, $C_{18}H_{15}O_2N_3Ac$, was obtained as a white cryst. powder from ligroin, m. 123° . With vanillin *5-p-hydroxy-m-methoxyphenyl-1-phenyl-3-hydroxy-1,2,4-triazole* was sepd. as prismatic needles from $EtOH$, m. $299-301^\circ$; *hydrochloride*, $C_{18}H_{15}O_2N_3.HCl.H_2O$, crystals, lose HCl at 100° and m. $299-301^\circ$; *acetyl derivative*, $C_{18}H_{15}O_2N_3Ac$, gave white needles from $AcOH$ or C_6H_6 , m. 149° .

E. J. WITZEMANN.

Phenylhydrazine. IV. Cryoscopic measurements on its capacity for forming phenylhydrazones. BERNARDO ODDO. Univ. Pavia. *Gazz. chim. ital.* **45**, I, 262-82 (1915); cf. *C. A.* **8**, 667.—By studying anhydrous $PhNHNH_2$ as a cryoscopic solvent, O. has found that while it acts normally with certain classes of substances like hydrocarbons, alcs., phenols, acids and bases, with aldehydes and ketones the well-known condensation takes place and causes a lowering of the f. p. from which the mol. wts. of the $C:O$ compds. may be calcd. and found to be one-half of the theoretical value. O. has made expts. to det. whether criteria for a comparison of the aldehyde or ketone function of a given compd. will be obtained if the lowering of the f. p. for the different substances in equimol. amts. of $PhNHNH_2$ is detd. for certain time intervals. The f. p. of anhydrous $PhNHNH_2$ is 19.35° . Three very different ketones ($AcMe$, $AcPh$ and $BzPh$) were studied in this way and showed marked differences in the time necessary to form phenylhydrazones as shown by the time rate of fall in the f. p. The results are plotted in curves with the times as abscissa and the temps. as ordinate. O. detd. whether the method could be used in establishing small differences in the reaction velocity.. For this purpose aliphatic ketones with and without Me groups adjacent to the $C:O$, ketones with aliphatic and aromatic radicals and ketones of the cyclohexane series were compared with ordinary acetone. The cyclohexanones were studied with especial care because under ordinary conditions they yield phenylhydrazones but also under certain conditions they give tertiary alcs. through a mol. rearrangement, as in Ac_2O in which the corresponding ester is obtained. Some aliphatic and aromatic aldehydes were also investigated. The following compds. were studied: $AcMe$, $AcPr$, $iso-PrAc$, $AcBu$, $iso-BuAc$, AcC_6H_{13} , Et_2CO , Pr_2CO , $(iso-Bu)_2CO$, $(C_6H_{11})_2CO$, $BzMe$, $BzEt$, $BzPr$, cyclohexanone, *o*-, *m*- and *p*-methylcyclohexanone, acetic, isobutyric, caproic and nonylic aldehydes, BzH , *p*- MeC_6H_4CHO , salicylaldehyde and piperonal. The % of the ketones used varied from 1.12 to 3.55 and the $PhNHNH_2$ from 98.88 to 96.45, by wt. In mol. % they varied from 1.29 to 2.76 for the ketone and 98.61 to 97.23 for the $PhNHNH_2$. With the aldehydes because of their smaller solubility the ratios used were about 99.50 mol. % $PhNHNH_2$ and 0.50 mol. % aldehyde. The results of the individual expts. are given in tables and curves and cannot be briefly abstracted. The main results are as follows: In the homologous series of methyl aryl ketones there is a progressive increase in the time necessary to produce a definite lowering of the f. p. due to the condensation which increases each time with the addition of CH_2 . The isomer with the branched chain (the *iso* deriv.) always required more time than the

corresponding straight chain deriv., *i. e.*, reacts more slowly. A similar serial progression was found with the ketones which do not have a Me adjacent to the CO. Moreover there were marked differences between the behavior of the methyl aryl ketones and the corresponding sym. ketones of the same mol. wt. The Me aryl ketones showed a marked difference in comparison with (iso-Bu)₂CO which shows a sharply diminished reaction velocity. The other ketones show a small but definite difference in the reaction velocities for the homologous ketones, MeBz, EtBz and PrBz, but the difference is more sharp in the case of the pure aliphatic ketones. The difference is very marked in comparison with cyclohexanones, the reaction velocity of which is greater than that of the ketones with 2 aliphatic radicals regardless of whether the latter have a Me group adjacent to the CO or not. Only in *o*-methylcyclohexanone was a noticeably slower reaction velocity noticed and this was no doubt due to the Me group being in the *o*-position. With aldehydes the greater reaction velocity of the aromatic aldehydes as compared with the aliphatic ones is notable. In the homologous series of aliphatic aldehydes there is a marked diminution in the velocity of reaction as the number of CH₂ groups is increased. The aldehydes in general react somewhat more easily than the ketones; the cyclohexanones are an exception. The latter stand next to the aromatic aldehydes as far as velocity of reaction is concerned. V. The behavior of phenylhydrazine semihydrate as a cryoscopic solvent. *Ibid* 283-92.—In an earlier paper (*C. A.* 8, 667), O. detd. the equil. point on the binary system PhNHNH₂ + H₂O and found a eutectic f. p. at 16° for the system PhNHNH₂ + phenylhydrazine hydrate and a max. in the mol. ratio of 66.38 of PhNHNH₂ for 33.62 of H₂O, which led to a hydrate with the formula (PhNHNH₂)₂.H₂O, of which the m. p. is 25.2° and which was called phenylhydrazine semihydrate. Expts. are described in which the behavior of this semihydrate as a cryoscopic solvent was studied in order to det. the effect of H₂O on the condensation and addition reactions described in part in the preceding abstract. The cryoscopic const. of the semihydrate was previously detd., with Ph₂, C₁₀H₈ and veratrole, to be $K \times 44.15$, but new detns. were made with dibenzyl (av. of 5 detns. 44.27) and safrole (av. from 6 detns. 42.81) and the mean value 43.54 was found. O. has used the old value, however, because only safrole and not the hydrocarbon caused marked variations from it. The latent heat of fusion of the semihydrate was calcd. from van't Hoff's formula as 40.28. Using the semihydrate as the solvent the following compds. were studied: C₆H₆, PhMe, *p*-xylene, cymene, Et, Pr and iso-Bu alcs., glycol, Ph₂COH, phenol, *p*-cresol, β -naphthol, resorcinol, eugenol, BzOH, salicylic acid, pyridine, piperidine, PhNH₂, PhNMe₂ and quinoline. From the results which are recorded in tables it is shown that all these compds. behave in a normal way. The values are, therefore, directly comparable with those obtained with dry PhNHNH₂. With the hydrocarbons there is a progressive increase in the mol. wt. with increase in the concn. The alcs. show the same characteristic, only less markedly. With the phenols, acids and bases values are obtained for the mol. wts. which are very close to the normal calcd. values. E. J. W.

Diethyl succinosuccinate. A study of its constitution, some derivatives, and absorption spectra. H. D. GIBBS AND H. C. BRILL. Bureau Sci., Manila, P. I. *Philippine J. Sci.* 10A, 51-65 (1915).—When the mother liquor from which a considerable quantity of Et succinosuccinate (I) has been obtained is concd., a small amt.

(I)

(II)

of a yellow cryst. substance (II) seps. (I) is but slightly colored, m. 127°, and analyzes (Meyer's method) for 90% enol form, while (II) is yellow, m. 123°, and is practically all in the *keto* form. (I) treated in alc. with concd. HCl and Zn dust, gives a cryst.

reduction product (a), pptd. from PhMe by alc., m. 120° ; the soln. in alkali turns brown in the air. *Acetyl derivative of (a)*, m. 167° and becomes yellow on heating. *Methyl acetylsalicylate (b)*, from $\text{HOC}_6\text{H}_4\text{CO}_2\text{Me}$ and AcCl in the presence of $\text{C}_6\text{H}_5\text{N}$, b. 265° , b₇ 122° . The absorption spectra of (I), (II), the diacetate, diimide, and (b) are given.

NORMAN A. SHEPARD.

Basic mercuric salicylate and methylsalicylate. Mercuric anisate. Mercuric m- and p-hydroxybenzoates. H. LAJOUX. *J. pharm. chim.* 11, 279-86(1915).—Neutral $(\text{HOC}_6\text{H}_4\text{CO}_2)_2\text{Hg}$ upon boiling with H_2O forms $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$ and stable, basic Hg salicylate which does not give the Hg^{++} tests. L. adopts for it the formula of Buroi (1902) $\text{HOC}_6\text{H}_4\text{CO.O.Hg}$ in the place of $\text{C}_6\text{H}_4\text{CO.O.Hg.O}$ held by him pre-

viously, and gives exptl. proof, showing that when the OH group is blocked by Me, Hg will not affect the OH group, but enters the nucleus. Mix equal amts. of $\text{MeOC}_6\text{H}_4\text{CO}_2\text{H}$ and $\text{Hg}(\text{OAc})_2$ with H_2O to a firm paste; after some hrs. dry on a H_2O bath. When treated with boiling H_2O basic mercuric methylsalicylate, $\text{MeOC}_6\text{H}_4\text{CO.O.Hg}$,

seps. as a pasty, adhesive mass, sol. in CHCl_3 , insol. in NaOH , which does not form yellow HgO . The place where Hg enters the nucleus was found to be in the *p*-position, since anisic acid yielded Hg anisate, but no basic salt upon boiling with H_2O . At 140 – 50° , however, basic salts were formed, probably in the *m*-position (cf. $\text{Hg}(\text{OBz})_2$; Dimroth, 1902). Analogous basic salts form readily with *m*- and *p*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$, but the reactions are more complex, owing to the more pronounced acid character of the OH group.

S. WALDBOTT.

Derivatives of phenyl ether. ALFRED N. COOK AND FRANK F. SHERWOOD. *J. Am. Chem. Soc.* 37, 1835-9(1915).— $2,4\text{'-O}_2\text{NC}_6\text{H}_4\text{OC}_6\text{H}_4\text{Me}$ (a) has been obtained in better yield than formerly (*Am. Chem. J.* 24, 525 (1900)) by heating *o*- $\text{O}_2\text{NC}_6\text{H}_4\text{Br}$ and *p*- $\text{KOC}_6\text{H}_4\text{Me}$ at 125° until reaction ceases and then gradually to 160° . With concd. HNO_3 on the H_2O bath it slowly gives a hexanitromethyldiphenyl ether, $\text{Me}(\text{O}_2\text{N})_6\text{C}_{12}\text{H}_2\text{O}$, m. 103 – 5° , probably identical with the compd. obtained by nitrating $4,4\text{'-O}_2\text{NC}_6\text{H}_4\text{OC}_6\text{H}_4\text{Me}$ (*J. Am. Chem. Soc.* 25, 64 (1903)). *Bromo-2-nitro-4'-methyl-diphenyl ether*, from (a) in CS_2 with a large excess of Br and a trace of I allowed to stand 2-3 days, yellow, m. 23° , reduced by Sn and alc. HCl on the H_2O bath to the stable 2-amino ether, whose chloroplatinate forms yellowish cryst. grains. "2-Nitro-4'-methylphenyl ether sulfonic acid" (sulfo-2-nitro-4'-methyldiphenyl ether) (b), from the Pb salt with H_2S , yellow, fumes on the H_2O bath even when dissolved in considerable H_2O , gives dense fumes with NH_3 vapors, is appreciably carried over when air is drawn through its aq. soln. or over the dry solid; all of its salts are anhydrous; with Sn and HCl on the H_2O bath its Cu salt gives the 2-amino acid. *Lead 2-nitro-4'-methylphenyl ether carbonate*, from the "mother substance" in dil. H_2SO_4 containing a little SO_2 with PbCO_3 ; *barium salt*, similarly obtained with BaCO_3 , slightly yellow radial aggregates; *strontium salt*, light yellow; *copper salt*, from the Ba salt and CuSO_4 , nearly white when moist, greenish when dry, easily reduced by Sn and HCl to a stable base; *cadmium salt*, yellowish white radial aggregates from H_2O ; *sodium salt*, light yellow. "2-Nitro-4'-methylphenyl ether sulfonyl chloride" (sulfonylchloro-2-nitro-4'-methyldiphenyl ether), from the Na salt of (b) with PCl_5 , light yellow plates from alc., m. 69° .

C. A. ROULLER.

Phenols. III. Preparation of some new substituted cresols. ARTHUR J. HILL AND LOUIS E. GRAF. *J. Am. Chem. Soc.* 37, 1839-46(1915); cf. Johnson and Hodge, *C. A.* 7, 3507.—5,2-Me(HO) $\text{C}_6\text{H}_3\text{Ac}$ (Betteridge, *Diss. Breslau*, 1898), obtained in 16 g. yield from 35 cc. AcCl slowly added to 30 g. *p*- $\text{MeC}_6\text{H}_4\text{OMe}$ in 200 cc. petr. ether and heated 30 hrs. with 25 g. AlCl_3 on the H_2O bath, light yellow needles from 80% alc.,

m. 50° ; 37 g. in 300 cc. HCl boiled 18 hrs. with 120 g. Zn-Hg gives 15 g. of *2-ethyl-4-methylphenol*, light yellow oil, b. $216-8^{\circ}$, darkens in the air; 5 g. heated 16 hrs. in a NaCl bath with 2.5 g. PhNCO and a little AlCl_3 gives 2 g. of the *phenylurethan*, $\text{PhN-HCO}_2\text{C}_6\text{H}_4\text{MeEt}$, square plates from alc., m. 101° . 5,2-Me(HO) $\text{C}_6\text{H}_3\text{COEt}$, obtained in 25 g. yield from 65 g. *p*-Me $\text{C}_6\text{H}_4\text{OMe}$, 72 g. AlCl_3 and 55 g. EtCOCl in 250 cc. petr. ether heated 30 hrs. on the H_2O bath, m. 2° , b. $153-4^{\circ}$, gives the Millon reaction; 32 g. digested 18 hrs. with 150 g. Zn-Hg and 250 cc. HCl gives 19 g. of *2-propyl-4-methylphenol*, light yellow, b. $128-30^{\circ}$, also obtained in 26 g. yield from 33 g. 5,2-Me(HO)- $\text{C}_6\text{H}_3\text{CH:CHMe}$ (a) (Claisen, C. A. 8, 64) and 38 g. Na in 300 cc. boiling alc.; *phenylurethan*, needles from alc. The allyl isomer of (a), on the other hand, could not be reduced with Zn-Hg in HCl, HI and P, or Na or Na-Hg in alc.; its *phenylurethan*, from PhNCO and AlCl_3 after 14 hrs. at 104° , thin needles from alc., m. 68° . 3-Ethyl-4-methylaniline is obtained by heating 19 g. 6,3-Me(AcNH) $\text{C}_6\text{H}_3\text{COCH}_2\text{Cl}$ 16 hrs. with 70 g. Zn-Hg in 300 cc. HCl; it is isolated as the *sulfate*, plates from dil. alc., m. 178° ; yield, 4 g. 2,4-EtMe $\text{C}_6\text{H}_3\text{NH}_2$, similarly obtained from 5,2-Me(AcNH) $\text{C}_6\text{H}_3\text{COCH}_2\text{Cl}$, b. $217-20^{\circ}$ (cf. Willgerodt and Brandt, *J. prakt. Chem.* 69, 436 (1904)).

CHAS. A. ROUILLER.

Hydantoina. XXXI. New synthesis of *o*-tyrosine. TREAT B. JOHNSON AND WALTER M. SCOTT. *J. Am. Chem. Soc.* 37, 1846-56(1915).—Having found that hydantoin does not condense smoothly with *o*-HO $\text{C}_6\text{H}_4\text{CHO}$ (a), J. and S. used 2-thiohydantoin (b) as the starting point; 37.5 g. (a), 30 g. (b) and 90 g. NaOAc heated 4 hrs. at $140-50^{\circ}$ in 230 cc. AcOH gave almost quant. 2-thio-4-*o*-hydroxybenzylhydantoin (c), radiating needles from AcOH, m. 248° ; heated 2 hrs. at $140-50^{\circ}$ with 3 parts $\text{CH}_2\text{ClCO}_2\text{H}$ and 8 parts H_2O , it gives 80% of 4-*o*-hydroxybenzylhydantoin (d), needles from alc., m. 271° (decompn.). 2-Thio-4-*o*-hydroxybenzylhydantoin, from 4 g. (c) in 45 cc. of 5% NaOH treated slowly at 75° with 150 g. of 3% Na-Hg, rosets of needles from H_2O , m. 107° , converted by 30% $\text{CH}_2\text{ClCO}_2\text{H}$ after 1 hr. at 130° into *o*-tyrosine-hydantoin, prisms from H_2O , m. $205-6^{\circ}$, better obtained (85% yield) from (d) in 1% NaOH at 80° with 3% Na-Hg. Long digestion with concd. Ba(OH)_2 (48 hrs. required for 7 g.) hydrolyzes it to *o*-tyrosine, decomp. $232-3^{\circ}$ on slow heating with formation of an oil which solidifies and m. again 270° ; on rapid heating it decomp. $247-50^{\circ}$; its *hydrochloride* seps. from dil. HCl in prisms, decomp. 180° . 2-Thio-4-*o*-methoxybenzylhydantoin (e), obtained in 20.5 g. yield from 10.3 g. (b), 12 g. *o*-MeOC $\text{C}_6\text{H}_4\text{CHO}$ and 30 g. NaOAc in 75 cc. AcOH heated 6 hrs. at $140-50^{\circ}$, needles from alc., m. 227° ; heated 4 hrs. at $130-40^{\circ}$ with 30% $\text{CH}_2\text{ClCO}_2\text{H}$ it gives 75% of 4-*o*-methoxybenzylhydantoin, prisms or needles from 95% alc., m. 178° . This is also obtained, but only in 2.2 g. yield, from 2.5 g. hydantoin, 3.5 g. MeOC $\text{C}_6\text{H}_4\text{CHO}$, 7.5 g. NaOAc and 25 cc. AcOH heated 4 hrs. at $130-40^{\circ}$. From 30 g. in 175 cc. of 10% NaOH and 300 cc. H_2O slowly treated at $80-90^{\circ}$ with 600 g. of 3% Na-Hg and warmed 3-4 hrs. is obtained 29 g. *o*-methoxybenzylhydantoic acid, rectangular prisms from alc., m. 189° (effervescence), quant. converted by hot dil. HCl into the *hydantoin*, prisms from alc., m. 186° . With concd. Ba(OH)_2 the hydantoic acid or the hydantoin give *o*-methoxyphenylalanine (4 g. from 7.5 g. acid), needles from H_2O , m. 206° (effervescence), 1.5 g. of which, heated 30 min. at 100° with 0.7 g. NH_4NCS , 8 cc. Ac_2O and 1 cc. AcOH, gives 2-thio-3-acetyl-4-*o*-methoxybenzylhydantoin, m. 168° , quant. hydrolyzed by HCl to 2-thio-4-*o*-methoxybenzylhydantoin, m. 190° , also obtained from (e) and Na-Hg in dil. alkali at $70-80^{\circ}$. XXXII. Synthesis of the hydantoin of 2-hydroxy-5-aminophenylalanine. *Ibid* 1856-63; cf. C. A. 6, 3089.—2-Thio-4-[2,5-dihydroxybenzyl]hydantoin, from (b), 2,5-(HO) $\text{C}_6\text{H}_3\text{CHO}$, NaOAc and AcOH heated 2 hrs. at $130-40^{\circ}$, prisms from dil. AcOH, decomp. about 270° , converted by $\text{CH}_2\text{ClCO}_2\text{H}$ into 4-[2,5-dihydroxybenzyl]hydantoin, decomp. above 300° , extremely unstable in alk. soln. and could not be reduced to the

PhCH₂ deriv. with Na-Hg. *2-Thio-4-[2-hydroxy-5-nitrobenzyl]hydantoin* (f), obtained in 22 g. yield from 15 g. 2,5-HO(O₂N)C₆H₃CHO, 9.7 g. (b), 29 g. NaOAc and 95 cc. AcOH heated 4 hrs. at 140°, does not m. below 300°, converted by CH₃ClCO₂H into *4-[2-hydroxy-5-nitrobenzyl]hydantoin*, needles from alc., m. 286° (yield 18 g. from 22 g. thio compd.); 14 g. boiled in 250 cc. concd. HCl with 28 g. Sn gave 11 g. of *4-[2-hydroxy-5-aminobenzyl]hydantoin hydrochloride*, corpuscular crystals from HCl, decomp. 242–3°, leaving a solid which does not m. 290°; 11 g. of this in 40 cc. H₂O at 5° slowly treated with 3 g. NaNO₂ in 10 cc. H₂O gives the diazonium salt as a light green powder which, after standing 30 min., is heated to about 60°, giving *4-[2,5-dihydroxybenzyl]hydantoin* as a red powder, slowly oxidizing and dissolving in NaOH with a dark color, sol. in HCl and H₂SO₄ with characteristic purple color, darkens on heating, partially decomp. about 170° but does not m. below 290°. Attempts to obtain with Ba(OH)₂ the corresponding NH₂ acid, which is probably an intermediate product in the formation of 2,5-(HO)₂C₆H₃CO₂H in alcaptonuria, failed; the hydantoin is extremely unstable in acid and alk. solns., apparently oxidizing and hydrolyzing to a dark amorphous product. *1-Methyl-4-[2-methoxy-5-nitrobenzyl]hydantoin*, obtained in 6 g. yield from 5 g. (f), 2 g. Na and 10 g. MeI heated 6 hrs. at 100° in 50 cc. MeOH, m. 265° (effervescence), reduced by Sn and HCl to *1-methyl-4-[2-methoxy-5-aminobenzyl]hydantoin hydrochloride*, light colored cryst. powder from H₂O, gradually decomp. above 170°, does not give a red color with Millon reagent.

CHAS. A. ROUILLER.

Nitrated proteins. I. Determination of the structure of nitrotyrosine. TREAT B. JOHNSON AND EDWARD F. KOHMANN. *J. Am. Chem. Soc.* 37, 1863–84 (1915).—As a preliminary to a projected investigation of the chem. of nitrated proteins, it became necessary to det. what compds. are formed on nitration of the aromatic NH₂ acid constituents of proteins. J. and K. find that on nitration tyrosine forms 2 isomeric NO₂ derivs., the chief product being that in which the NO₂ is in the *o*-position to the HO group. The nitration was carried out according to Städeler's directions (*Ann.* 116, 77 (1860)). When 5.7 g. of the crude product (a) in 150 cc. MeOH is gently digested 18.9 hrs. with 7 g. KOH and 34 g. MeI, it gives *o*-nitrotyrosinetrimethylammonium iodide (b), 4,3-HO(O₂N)C₆H₃CH₂CH(CO₂H)NMe₃I, yellow prisms with 2 H₂O from alc., m. 119°, decomp. 121°, gives the Millon reaction; and the more sol. *diquaternary salt* (c), provisionally assigned the structure RCH(NMe₃I)CO₂NMe₃CHRCO₂H (R = HO-(O₂N)C₆H₃CH₂), stout prisms from 95% alc., m. 220–1° (decompn.), gives the Millon reaction. Yields, 10 g. (b) and 6 g. (c) from 16 g. (a). When boiled with 10% NaOH (a) gives NMe₃ and 92% of 4,3-HO(O₂N)C₆H₃CH:CHCO₂H (*C. A.* 9, 596); no evidence was obtained of the formation of any other acid. The acid is also obtained in 79% yield from (c). With Sn and HCl on the H₂O bath it yields *3-amino-4-hydroxycinnamic acid hydrochloride*, needles from dil. HCl, begins to change 225°, decomp. 240°. With NH₄CNS and Ac₂O, (a) yields various products, depending on the conditions. In 1 expt. 12 g. (a), 6.3 g. NH₄CNS and 60 cc. Ac₂O were heated 20 min. on the H₂O bath, cooled and poured into 400 cc. cold H₂O; there sepd. 14.5 g. of a red oil which finally solidified; when dissolved in 100 cc. AcOH, digested with charcoal and cooled, there sepd. 0.2 g. of *2-thio-1,3-diacetyl-4-[3-nitro-4-acetoxybenzyl]hydantoin*, yellow needles with 1 AcOH, m. 174°. The AcOH filtrate on concn. to 20 cc. deposited 2.7 g. of *2-thio-3-acetyl-4-[3-nitro-4-acetoxybenzyl]hydantoin*, yellow rectangular plates from AcOH, m. 173–5°. The combined AcOH filtrates, evapd. to dryness and digested with excess of concd. HCl for 1.5 hrs., gave *2-thio-4-[3-nitro-4-hydroxybenzyl]hydantoin* (d), yellow hexagonal plates from AcOH, m. 239–42° (decompn.), and about 0.1 g. of the *o*-nitro isomer (e), yellow needles with 1 AcOH which it loses at 110°, becoming brick-red; it begins to char at 270° and

slowly decomp. further when heated higher. Its formation shows that the crude (a) contains, besides much 4,3-HO(O₂N)C₆H₄CH₂CH(NH₂)CO₂H, a little of the 4,2-compd. More (e) in the yellow and red forms is obtained when the H₂O from which the red oily condensation product seps. (see above) is evapd. to dryness with HCl and the residue is crystd. from AcOH. When the condensation was repeated with 12.7 g. (a), 6.5 g. NH₄CNS and 64 cc. Ac₂O and the 16 g. oil sepg. from H₂O was crystd. from 95% alc. instead of AcOH, no di- and tri-Ac derivs. were obtained, but, instead, flat prisms, m. 176–8°, consisting chiefly of 2-thio-3-acetyl-4-[3-nitro-4-hydroxybenzyl]-hydantoin, hydrolyzed by hot concd. HCl to (d); the alc. filtrate on concn. yielded 0.5 g. of the 2 forms of (e). 4-[3-Nitro-4-hydroxybenzyl]hydantoin (f), obtained quant. from (d) with 30% CH₂ClCO₂H, yellow needles with 1 AcOH, m. 225–6°, gives the Millon reaction; it is also obtained in 0.5 g. yield from 3 g. 4-[3-nitro-4-methoxybenzyl]-hydantoin heated at 100° for 3 hrs. with AcOH satd. at 0° with HBr. 2-Thio-4-[3-nitro-4-methoxybenzyl]hydantoin, obtained in 10 g. yield from 10 g. 2-thio-3-benzoylhydantoin, 8.2 g. 4-3-MeO(O₂N)C₆H₄CHO and 16 g. NaOAc heated 2.5 hrs. at 155° in 50 cc. AcOH, stellar crystals from dil. alc., flat prisms from dil. AcOH, begins to darken 240°, decomp. 255°, converted by CH₂ClCO₂H into 4-[3-nitro-4-methoxybenzyl]-hydantoin which with HI and red P and subsequent treatment with AgCl gives the aminohydantoin-HCl, sepg. from HCl in anhydrous prisms, decomp. about 285°, also obtained when the hydantoin prepd. from (a) is similarly treated. 1-Methyl-4-[3-nitro-4-hydroxybenzyl]hydantoin, from (f), KOH and 1 mol. MeI in MeOH heated 2 hrs. at 150–5°, minute yellow prisms, m. 202°, gives a red color with Millon's reagent; with 3 mols. KOH and 4 of MeI is obtained the 1,3-dimethyl compound, microcrystals, m. 180–5°, gives a positive Millon test. 2-Thio-4-anisalhydantoin is obtained in 45 g. yield from 23 g. 2-thiohydantoin, anisaldehyde and NaOAc in AcOH; 5 g. in dil. NaOH slowly treated at 75° with 100 g. of 3% Na-Hg gives 4.5 g. 2-thio-4-anisylhydantoin, plates from AcOH, m. 215°.

C. A. ROULLER.

Use of cyanic acid in glacial acetic acid solution and in mixtures of glacial acetic acid with certain organic solvents. Derivatives of 1-isobutyric acid amino-5-dimethylhydantoin. J. R. BAILEY AND W. T. READ. *J. Am. Chem. Soc.* 37, 1884–93 (1915).—[In the following R = Me₂C.CO.NH.CO.N.] Whereas HCNO does not

react with (NHCMe₂CO₂Et)₂ (a) in H₂O, when 35 g. (a) in 70 cc. AcOH is treated below 40° in the course of 45 min. with 18 g. KCNO and after 1 hr. is heated 30 min. at 60°, there is obtained 80% of ethyl-1-isobutyrate amino-5-dimethylhydantoin ([1-isobutyroxyamino]-5,5-dimethylhydantoin) (b), RNHCMe₂CO₂Et, plates like rhombic prisms from 50% alc., m. 104–5°, insol. in cold dil. acids, slowly dissolves, with loss of the CMe₂CO₂Et group, in hot 50% H₂SO₄, reduces cold Br-H₂O instantaneously, KMnO₄ slowly. In its prepn. mixts. of AcOH with various org. solvents can be used within certain limits without materially affecting the yield, and the reaction also takes place, but with diminished yield, in aq. AcOH containing more than 30% acid. The free (NHCMe₂CO₂H)₂ or its nitrile instead of (a) could not be condensed with HCNO. With Br in dil. alc. or 50% AcOH (b) gives what is probably the bis compound (NRCMe₂CO₂Et)₂, non-volatile oil, d. 1.0524, decomp. about 110° in vacuo with gas evolution and sublimation of what is probably RH. With NaNO₂ in AcOH, (b) gives the nitroso derivative RN(NO)CMe₂CO₂Et, thin, faintly yellow plates from H₂O, m. 104°, gives the Liebermann reaction, hydrolyzed by warming for 30 min. with a slight excess of concd. KOH to the free nitroso acid, minute rhombic plates from H₂O, m. 165° (decompn.). 1-Isobutyroxyamino-5,5-dimethylhydantoin, similarly obtained from (b), slender, prismatic plates from H₂O, m. 192.5°, decomp. above 200°. 1-Amino-5,5-dimethylhydantoin, from (b) heated 4 hrs. at 110° in 50% H₂SO₄, slender prisms from

AcOEt, m. 170° , reduces cold Br-H₂O, KMnO₄ and HgO, depositing a very small amt. of an oxidation product, probably a tetrazene; boiled 1 hr. in AcOEt with 1 mol. BzCl it forms the 1-benzoylamino derivative, m. 241° ; while in H₂O with the calcd. amt. of BzH it gives quant. the 1-benzylideneamino compound, needles from alc., m. $191-2^{\circ}$; the latter can also be obtained in 4.6 g. yield from KCNO in 50 cc. AcOH and 5 g. PhCH:NNHCHMe₂CO₂H which is obtained in 42% yield from 20 g. N₂H₄·H₂SO₄ and 21.2 g. K₂CO₃ in 50 cc. cold H₂O treated with 17.8 g. acetone and 1 mol. concd. NaHSO₄, then, after 2 hrs., with 10 g. KCN, allowed to stand 24 hrs. with 2 vols. concd. HCl, boiled 1 hr., concd. *in vacuo*, dissolved in a little H₂O, treated with excess of NaOAc and then in the usual way with BzH. Its Et ester with HCl and KCNO gives no hydantoin but NH₂CONHNHCHMe₂CO₂Et.

CHAS. A. ROUILLER.

Reactions of sodium malonic ester. II. C. LORING JACKSON AND F. C. WHITMORE. *J. Am. Chem. Soc.* 37, 1915-34(1915); cf. *C. A.* 9, 2089.—In this paper is proven the 2nd part of J.'s theory of malonic ester reactions, *viz.*, that the course of the reaction depends in great measure on the relative attractions of the 2 parts of the substance added for the C attached to the Na. A list is given of 29 well-established cases in which the halogen of an org. compd. is replaced by H or Na under the influence of a Na ester; all have 1 thing in common—the compds. contain strongly negative radicals, the negativity being produced in a great variety of ways (nitrohalogenphenyl, O compds. of S, S alone, or reinforced by O₂NC₆H₄, PhC:C, CO₂R, Ph ketones or imides of dibasic acids). Ten cases are also discussed in which the radical combined with the halogen is negative but perhaps not enough so to be preferred to the halogen by the positive C. Only 1 does not harmonize with the theory; CNCl and CHNa(CO₂Et)₂ (a) give NCCH(CO₂Et)₂ while CNBr gives HCN and [CH(CO₂Et)₂]₂ (b) although Br is certainly more negative than CN and therefore NCCH(CO₂Et)₂ should be formed instead of HCN. This may be due to the intervention of other conditions, such as differences in solubility of the products or of constitution of the CN compds. The (a) from 3.5 g. Na and 28 cc. CH₂(CO₂Et)₂ in several vols. Et₂O was treated with PhSO₂Cl in 20 cc. each of C₆H₆ and Et₂O and the heavy white ppt. which at once formed was allowed to stand in the cold 10 days, during the course of which NaOEt from 3.5 g. Na was slowly added; the ppt. was then filtered and washed with Et₂O; the washings yielded (b), while the insol. residue, when exhd. with hot alc., gave PhSO₂Na and a salt sol. in cold alc. and having the comp. of diethyl sodiophenylsulfomalonate, PhSO₂CNa(CO₂Et)₂ (c). Equiv. amts. of CHCl(CO₂Et)₂ and PhSO₂Na in MeOH at once gave a ppt. of NaCl and the filtrate, when made barely alk. to phenolph. with NaOH in MeOH and evapd., gave (c). [2,4-(O₂N)₂C₆H₃S]₂ and 1 mol. Br₂ in CCl₄ gave a ppt. insol. in org. solvents (containing 21.94% Br instead of the 28.67% calcd. for the compound (O₂N)₂C₆H₃SBr, showing it contained some unchanged disulfide), blackens about 120° , gives HBr when boiled with H₂O. With 2 mols. (a) in C₆H₆, it turned red and almost completely dissolved; after 2 days the soln. turned pale yellow and deposited a heavy ppt., the filtrate from which, after shaking with dil. H₂SO₄, yielded on evapn. a small amt. of (O₂N)₂C₆H₃SH. Extn. of the ppt. with various solvents yielded noncrystallizable oils and the undissolved portion was probably mostly the disulfide, although it m. around 260° (decompn.) instead of 280° . BzI and (a) give chiefly BzCH(CO₂Et)₂ but if the oil containing it is shaken with warm H₂O and the ext. is mixed with an equal vol. of AcOH and treated with PhNHNH₂, there is formed a small amt. of a solid m. 163° after crystn. from alc.; when mixed with PhCH:NNHPh, m. 158° (prepd. from BzH and PhNHNH₂), it m. 160° , while with BzNHNHPh, m. 168° (from BzI and PhNHNH₂), it m. $135-40^{\circ}$. This indicates, but does not prove definitely, that the product of the reaction of BzI with (a) contains some BzH. From *p*-O₂NC₆H₄COCl, CH₂(CO₂Et)₂, in Et₂O and Na in alc. allowed to stand 4 days is obtained diethyl *p*-nitro-

benzoylmalonate, needles from MeOH, m. 93° . $\text{BrC}(\text{CO}_2\text{Et})_2$ and (a) allowed to stand 9 weeks in $\text{Et}_2\text{O}-\text{C}_6\text{H}_6$ gave 67% of (b) and, apparently, $\text{CH}(\text{CO}_2\text{Et})_2$, b₄ $170-5^{\circ}$. From $\text{Ph}_2\text{CHCHBrBz}$ in C_6H_6 and 2 mols. (a) are obtained 76% $\text{Ph}_2\text{CHCH}_2\text{Bz}$, 54% (a) and apparently $\text{CHBr}(\text{CO}_2\text{Et})_2$. Bischoff's work (*Ber.* 29, 1510, 1515 (1896)) has been repeated with the Br and Me compds. in the cold; 5 g. $\text{MeCBr}(\text{CO}_2\text{Et})_2$ in 1 vol. C_6H_6 were added to 15.8 g. $\text{CH}_2(\text{CO}_2\text{Et})_2$ in C_6H_6 , previously treated with the NaOEt from 2.2 g. Na, and allowed to stand 3 weeks in the cold; there was then obtained 4.3 g. (68%) of (b); no $[(\text{EtO}_2\text{C})\text{C}]_2$ (d) was detected although some may have been present in the oil. In another expt. 0.9 g. (b) was obtained from 5 g. $\text{CHMe}(\text{CO}_2\text{Et})_2$ and the NaOEt from 0.66 g. Na in C_6H_6 slowly added to 34.3 g. $\text{CHBr}(\text{CO}_2\text{Et})_2$ in C_6H_6 and allowed to stand 3 weeks. The fact that B. obtained (d) was therefore due to his working with boiling solvents. Picryl chloride and $\text{MeCNa}(\text{CO}_2\text{Et})_2$ gave flat, straw-colored needles, m. $78-9^{\circ}$, which were undoubtedly *diethyl trinitrophenylmethylmalonate*, but they were so explosive that no good analyses could be obtained. (a) and nitro- and dinitrobenzyl iodides and the corresponding thiocyanates, triiodoresorcinol and tetrabromo-o-quinone yielded unmanageable oils. $(\text{IC} \cdot)_2$ did not react either in alc., Et_2O or C_6H_6 . $p\text{-O}_2\text{NC}_6\text{H}_4\text{CH}_2\text{SCN}$ (Henry, *Ber.* 2, 638 (1869)), pale yellowish needles or slender prisms from alc., m. $85-6^{\circ}$. *2,4-Dinitrobenzyl thiocyanate*, pale yellow prisms, m. $86-7^{\circ}$. Both thiocyanates have an irritating action on the skin and may produce serious poisoning.

CHAS. A. ROUILLER.

Esterification. VI. Esterification of benzoic acid by mercaptans. L. S. PRATT AND E. EMMET REID. *J. Am. Chem. Soc.* 37, 1934-48(1915); cf. *C. A.* 4, 2270.—The BzSMe used, b₂₈ 134° ; d₂₈ 1.1381 (Obermeyer, *Ber.* 20, 2922 (1887), gives b₇₆₀ $231-2^{\circ}$), was prepd. from Me_2SO_4 and BzSH nearly neutralized with KOH. The BzSEt , b₂₁ 146° , d₂₆²⁵ 1.0977, and BzSPr , b₁₁ 144° , d₂₆²⁵ 1.0724, were made by Wheeler's method (*Am. Chem. J.* 24, 69 (1900)). An electric furnace, described in detail, was constructed, whereby temps. ranging from 200° to 300° could be maintained const. to within 4° . The reaction tubes, containing $\text{BzOH} + \text{mercaptan}$ or $\text{thiol ester} + \text{H}_2\text{O}$, after being heated and then cooled with ice-NaCl were broken and dropped into a flask, covered with alc. (distd. from KOH), freed of mercaptan with a current of CO_2 -free air at 50° and the BzOH titrated with $\text{Ba}(\text{OH})_2$ and phenolph. From the results of the numerous measurements, P. and R. find that while very concordant results are obtained in the acid + mercaptan series, the ester + H_2O series, for some reason which has not yet been discovered, show wide variations. In all the expts. the heating was so long (100-400 hrs.) that the reaction nearly reached the limit, the values from the acid and ester series differing in most cases by less than 2%. In the case of the Me ester no decompn. was noted at 243° ; in that of the Et ester there was slight decompn. at 243° but none at 220° ; in that of the Pr ester, slight decompn. occurred at 220° . Only slight traces of H_2S were found in expts. at 270° but at this temp. the decompn. in the case of the Et ester was so great as to completely vitiate the results. The following are the % limits of esterification (calcd. for equimol. mixts.) obtained with the various mercaptans at 220° and 243° , resp.: Me, 18.7, 19.6; Et, 14.7, 15.4*; Pr, 14.1*, 15.1* (14.3 at 193°); iso-Bu, —, 12.7*; iso-Am, —, 10.8* (slight decompn. in the cases marked*). Apparently, rise in temp. slightly raises the limit. The proportions of acid and mercaptan or of ester and H_2O have no appreciable influence on the limit.

CHAS. A. ROUILLER.

Phenolquinolinein, a heterocyclic analog of phenolphthalein. ARTHUR W. DOX. *J. Am. Chem. Soc.* 37, 1948-9(1915).—From 10 g. quinolinic anhydride (obtained quant. by gently warming the acid with 2 parts Ac_2O until dissolved and then boiling 5. min.), 20 g. PhOH and 8 g. concd. H_2SO_4 heated 10 hrs. at 120° , poured into H_2O and freed from excess of PhOH by boiling is obtained a yellow granular ppt. which,

after boiling in alc. with charcoal, gives an almost colorless soln. turning milky on evapn. and diln. with H_2O and depositing a yellowish granular sediment containing 4.50% N (calcd. for $C_{12}H_{11}O_4N$, 4.56%), gives with alkalis an intense pink color at once discharged by acids.

CHAS. A. ROUILLER.

Constitution of the 4,4'-dichlorodinitro- and 4,4'-dibromodinitrobenzophenones obtained by nitration of 4,4'-dichloro- and 4,4'-dibromobenzophenones. P. J. MONTAGNE. Univ. Leyden. *Ber.* 48, 1027-37(1915); cf. *Rec. trav. chim.* 21, 26 (1902); Consonno, *Gazz. chim. ital.* 34, 374(1904); Maron and Fox, *C. A.* 9, 307; Schöpf, *Ber.* 24, 3774(1891).—M. shows that the 2 compds. are 4,4'-dichloro- (a) and 4,4'-dibromo-3,3'-dinitrobenzophenone (b). (a), m. 132.5° (C. gives 120°, M. and F. 132-3°), is reduced by $SnCl_2$ and HCl to the 3,3'-diamino compound, light yellow needles from alc., m. 167.5°. 4,3'-Br(O_2N) C_6H_3 (4-Br C_6H_4)CO, from $PhBr$, $AlCl_3$ and 4,3-Br(O_2N) C_6H_3 COCl (which, contrary to Grohmann, *Ber.* 23, 3446 (1890), b₁₀ 178° without decompn.), m. 119.5°, b₁₀ 287°, seps. from $AcOEt$ in wine-yellow, monoclinic, apparently sphenoidic crystals, $a:b:c = 2.6352:1:4.4498$, β 89° 10' 45", c (001), s (101), r (10 $\bar{1}$), q (0 $\bar{1}$ 1), k (011), o' ($2\bar{1}$ 3). (b), m. 157.5°, boiled 1.5 days with $SnCl_2$, HCl and alc., gives the 3,3'-diamino compound (c), m. 178.5-9.8° (yield, over 80%). 4,4'-Diamino-3,3'-dinitrobenzophenone (d), from (a) or (b) and alc. NH_3 heated 1-2 days at 150°, red needles from alc., m. 293.5° (C. gives 121°, M. and F. 287-9°). 4,4'-Di-anilino compound, from (a) or (b) and alc. $PhNH_2$ after 1 day at 150°, yellow-brown, m. 226.5° (C., 212°). 3,4,3',4'-Tetraaminobenzophenone, from (d), $SnCl_2$, HCl and alc., long, yellow needles, sepg. from H_2O in anhydrous or hydrated form, depending on the concn. and temp., m. (anhydrous) 217° (C., 155°); with phenanthraquinone in boiling $AcOH$ it gives di[phenanthrophenazine] ketone, generally m. 378-80°, sometimes lower (C., 160°). ($m-O_2NC_6H_4$) CH_2 (Thorpe and Wildman, *C. A.* 9, 1067), m. 175.5°, gives on oxidation ($m-O_2NC_6H_4$) $_2$ CO, m. 155°, also obtained by nitration of Ph_2CO ; reduced by Baeyer's method (*C. A.* 1, 2697) it gives the di- NH_2 compd., m. 150.5° (B., 173°), which with $Na-Hg$ in boiling alc. (Staedel, *Ann.* 218, 351) yields ($m-H_2NC_6H_4$) $_2$ CHOH, m. 128.5°, identical with the product obtained from (c) and $Na-Hg$.

CHAS. A. ROUILLER.

Isatin. A. BINZ AND R. HUETER. Berlin. *Ber.* 48, 1038-41(1915).—Isatin (a) reacts with $p-C_6H_4(NH_2)_2$ (b) in 2 ways, depending on the exptl. conditions. Thus, 7.5 g. (a) and 5 g. (b) in 100 cc. of 80% alc. boiled a short time and allowed to stand 24 hrs. quant. give p -aminophenylisatin (c), $H_2NC_6H_4N:C.CO.NH.C_6H_4$, ruby-red

needles from alc., m. 239-41° (decompn.), gives with BzH a yellow benzylidene derivative which could not be recrystd. without decompn.; with $NaOEt$ in alc. with a little Et_2O is formed, without change in color, a sodium salt, $C_{14}H_{10}ON_2Na$, which with 5% $AgNO_3$ yields the dark silver salt; with $NaOH$ and hydrosulfite is formed a vat imparting to cotton only a faint and not fast color; with 10 parts of com. H_2O_2 (carefully neutralized with $NaOH$) is obtained aminophenylisatoic anhydride, black microscopic needles which cannot be recrystd., m. around 232°, gives a sulfonation product insol. in H_2O . p -Aminophenyldibromoisatin, from equimol. amts. of dibromoisatin and (b) in aq. alc., red-violet, m. above 300°. If 16 g. (a) and only 5 g. (b) are boiled a short time in 150 cc. of 80% alc. or if (c) is warmed with $AcOH$ or with (a) in alc., the product is di-[p -aminophenylisatyl]imesatin (d), $(CO.NH.C_6H_4.C:NC_6H_4NH)_2C.CO.NH.C_6H_4$, yellow-red scales from C_6H_5N , m. 310° (decompn.), converted into (c) by warming with (b). (d) is also obtained from equimol. amts. of (a), (b)- HCl and $NaOAc$ (Möhlau and Litter, *J. prakt. Chem.* 73, 471(1906), assigned to this compd. the structure (c), probably owing to a faulty analysis).

CHAS. A. ROUILLER.

Salting out of amino acids and the separation of amino acids with the aid of neutral salts. P. PREIFFER AND FR. WITTKA. Univ. Zurich. *Ber.* 48, 1041-8(1915); cf.

C. A. 7, 1025, 3764.—Glycocoll, tyrosine and asparaginic acid are not salted out of their satd. solns. by satg. with the chlorides, bromides, sulfates of the alkalis, alk. earths and NH_4AlCl_4 , $\text{Al}_2(\text{SO}_4)_3$, KOAc , NaOAc and $(\text{CO}_2\text{K})_2$; alanine is salted out to the extent of 19% by $(\text{NH}_4)_2\text{SO}_4$. *dl*-Leucine and *dl*-phenylalanine, however, are pptd. to the following % extents, resp., at room temp.: $(\text{NH}_4)_2\text{SO}_4$, 78.2, 80.8; NaCl , 60.8, 57.4; KCl , 48.9, 38.4; Na_2SO_4 , 34.3, 31.4; MgSO_4 , 31.9, 66.4; AcONa , 31.4, 36.9; AcOK , 13.6, 25.8; $(\text{CO}_2\text{K})_2$, 39.2, 67.0. When to 70 cc. of a satd. phenylalanine soln. (about 0.976 g. NH_2 acid) is added 2 g. glycocoll and 49 g. $(\text{NH}_4)_2\text{SO}_4$, drained and dried at 90° , the ppt. is found to contain 0.8161 g. NH_2 acid which, by treatment with CuSO_4 and $\text{Ba}(\text{OH})_2$, was shown to consist almost entirely of phenylalanine. Similarly from 0.097 g. of *l*-leucine ($[\alpha] 8.2^\circ$) in 10 cc., treated with 0.1 g. glycocoll and 7 g. $(\text{NH}_4)_2\text{SO}_4$, was obtained a ppt. containing 0.0588 g. of NH_2 acid with $[\alpha] 8.5^\circ$; when 0.2 g. glycocoll was used, the pptd. NH_2 acid weighed 0.0575 g. and showed $[\alpha] 7.8^\circ$; from solns. free from glycocoll, about 61% of the *l*-leucine is pptd. As pointed out before, NH_2 acids form with neutral salts (especially CaCl_2) well-characterized compds., with resulting differences in solubility. The CaCl_2 compds. of glycocoll and *dl*-alanine differ markedly in their solubility in aq. alc.; 0.5 g. glycocoll and 10 g. $\text{CaCl}_2 \cdot 10\text{H}_2\text{O}$ in 8 cc. H_2O dild. with 120 cc. alc. and allowed to stand in the ice chest deposited 76.9% of the NH_2 acid as its CaCl_2 compd. while under the same conditions *d*-alanine gave no deposit. On the other hand, solns. identical to the above except that they contained no CaCl_2 deposited 92 and 82%, resp., of the two NH_2 acids. A mixt. of 0.5 g. each of the acids with 10 g. $\text{CaCl}_2 \cdot 10\text{H}_2\text{O}$ in 8 cc. H_2O and 120 cc. alc. gave 84.2% of almost pure glycocoll as the CaCl_2 compd. (the ppt. contained 25.08% of H_2O and, after dehydration, 27.17% Cl ; calcd. for $\text{CaCl}_2 \cdot 2\text{NH}_2\text{CH}_2\text{CO}_2\text{H}$, 27.01%), while the filtrate gave $[\alpha] 13.5^\circ$; calcd. value on the assumption that all the alanine had remained in soln., 14.0° . From the ppt. and the filtrate the 2 acids were isolated as the Cu salts by treating with Ag_2O or PbO , filtering, pptg. with H_2S , boiling to expel the excess of H_2S , treating with excess of NH_3 and $(\text{NH}_4)_2\text{CO}_3$, allowing to stand 24 hrs., filtering from the CaCO_3 , evapg. to dryness and boiling in H_2O with excess of $\text{Cu}(\text{OH})_2$. As $\text{Cu}(\text{O}_2\text{CCH}_2\text{NH}_2)_2$ forms with CaCl_2 a cryst., deep blue compd., $\text{CaCl}_2 \cdot (\text{NH}_2\text{CH}_2\text{CO}_2)_2\text{Cu} \cdot 3\text{H}_2\text{O}$, $\text{Cu}(\text{O}_2\text{CCH}_2\text{NH}_2)_2$ cannot be obtained directly from a soln. containing CaCl_2 . CHAS. A. ROUILLER.

Differences in reaction of stereoisomeric ethylene halides. II. P. PFRIFER with K. v. SWIDZINSKI. Univ. Zurich. Ber. 48, 1048-58(1915).—Just as with $(\text{PhCHBr})_2$ and 2,4-(O_2N) $_2\text{C}_6\text{H}_3\text{CHBrCHBrPh}$ (C. A. 6, 2736), so of the 2 stereoisomeric *o*- $\text{O}_2\text{NC}_6\text{H}_4\text{CHBrCHBrPh}$ the higher melting α -form loses Br_2 and the lower melting β -form HBr with $\text{C}_6\text{H}_5\text{N}$. The mixed *o*-nitrostilbene dibromides are obtained in 2.9 g. yield from 2 g. *o*- $\text{O}_2\text{NC}_6\text{H}_4\text{CH:CHPh}$ and 1.5 g. Br allowed to stand overnight in CS_2 ; they are sep'd. by crystn. from MeOH into the α -form, yellowish tables, m. 156° , and the β -form, more compact to prismatic crystals, m. 89° . From 0.5 g. of the α -form heated 6 hrs. on the H_2O bath with 6 g. $\text{C}_6\text{H}_5\text{N}$ is obtained *o*- $\text{O}_2\text{NC}_6\text{H}_4\text{CH:CHPh}$, while 3.2 g. of the β -form with 20 cc. $\text{C}_6\text{H}_5\text{N}$ gives 1.9 g. *o*-nitro- μ -bromostilbene, dark yellow oil. From 1 g. of $\text{PhCHBrCHBrCO}_2\text{H}$, m. 195° , heated 10 hrs. in 5 cc. $\text{C}_6\text{H}_5\text{N}$, is obtained a mixt. of about 62% $\text{PhCH:CHCO}_2\text{H}$ and 38% $\text{PhCH:CBrCO}_2\text{H}$, while the isomer, m. $83-91^\circ$, gives 0.6 g. of practically pure $\text{PhCH:CBrCO}_2\text{H}$. Similarly, the ester $\text{PhCHBrCHBrCO}_2\text{Me}$, m. 117° , gives a mixt. of about 40% $\text{PhCH:CHCO}_2\text{Me}$ and 60% $\text{PhCH:CBrCO}_2\text{Me}$, while the isomer, m. $50-2^\circ$, gives only the Br ester. The two $\text{MeCHBrCHBrCO}_2\text{H}$ behave alike, the form m. $56-60^\circ$ giving $\text{MeCH:CBrCO}_2\text{H}$, just like the isomer m. 87° (C. A. 5, 504). The same is true of the two $(\text{CHBrCO}_2\text{H})_2$, the form m. $160-4^\circ$ giving $\text{HO}_2\text{CC}(\text{:CH}_2)_2\text{C}_6\text{H}_4\text{NBr}$, while the isomer m. 250° gives, together with a little of the above compd., chiefly $\text{HO}_2\text{CCH:C.CO.O.C}_6\text{H}_4\text{N}$

(C. A. 5, 495), $\text{HO}_2\text{CCH}:\text{CBrCO}_2\text{H}$ therefore being an intermediate product in both cases. Coumarin dibromide gives monobromocoumarin. CHAS. A. ROUILLER.

Aromatic arsenic compounds. X. o-Carboxylated diaminodihydroxyarsenobenzene. P. KARRER. Georg-Speyer-Haus, Frankfurt a/M. *Ber.* 48, 1058-64 (1915).—*2-Carboxy-4-nitrophenylarsonic acid*, obtained in 22 g. yield from 18 g. 2,5- $\text{H}_2\text{N}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{CO}_2\text{H}$ in 100 cc. HCl (d. 1.12) and 50 cc. H_2O diazotized at 5° with 50 cc. of 2 *N* NaNO_2 , filtered, slowly treated with 26 g. Na_2AsO_3 in 50 cc. H_2O and then with 10 *N* NaOH until the acid reaction to Congo just disappears, druses and needles from H_2O , reduced by hydrosulfite to an easily sol. substance, probably a sulfaminic acid; 14.5 g. in 98 cc. of 10 *N* NaOH and 180 g. H_2O is poured into 86 g. crystd. FeSO_4 in 200 cc. H_2O at 70° , stirred thoroughly, drained off, extd. twice with 200 cc. boiling H_2O , the combined filtrates concd. until salts begin to sep., made acid to Congo with HCl (d. 1.19), cooled and filtered. The filtrate, containing the NH_2 acid, is dild. with 100 cc. H_2O , neutralized with 10 *N* NaOH , treated with 10 cc. concd. H_2SO_4 , diazotized at 5° with NaNO_2 until KI-starch paper momentarily gives a strong blue color, heated on the H_2O bath, filtered (owing to its solubility, the HO acid cannot be isolated directly), treated with 60 cc. of 35% H_3PO_3 and a little KI and heated on the H_2O bath 20-30 min.; the yellow ppt. of 2,2'-dicarboxy-4,4'-dihydroxyarsenobenzene thus obtained is treated, while still moist, with 3 cc. H_2O and, drop by drop, with 30% H_2O_2 to complete decoloration and soln., quickly filtered and cooled, 2-carboxy-4-hydroxyphenylarsonic acid sepg. in needles; 3.9 g. of this in 20 cc. concd. H_2SO_4 treated below 0° with 1.3 g. HNO_3 (d. 1.42) in 5 cc. H_2O , allowed to warm up to 10° and poured upon 75 g. ice, gives the 5-nitro derivative, needles, decomp. $350-5^\circ$; 2.2 g. of this heated to boiling with 20 cc. of 25% H_3PO_3 and 10 cc. AcOH deposits $[\text{5,4,2-O}_2\text{N}(\text{HO})(\text{HO}_2\text{C})-\text{C}_6\text{H}_3\text{As}]_3$ which on addition of 2-3 g. KI is energetically reduced and on diln. with 30 cc. H_2O and neutralization of the greater part of the acid with concd. NaOH the light yellow 5,5'-diamino-4,4'-dihydroxy-2,2'-dicarboxyarsenobenzene is obtained; it is easily sol. in soda, NaOH , NaHCO_3 and NaOAc , difficultly in dil. and concd. HCl , gives a red condensation product with $\text{Me}_2\text{NC}_6\text{H}_4\text{CHO}$, is easily diazotized; 0.3 g. in 10 cc. hot H_2O and a little NaOAc , heated 10 hrs. in a sealed tube in the H_2O bath, gives 3,4- $\text{HO}(\text{H}_2\text{N})\text{C}_6\text{H}_3\text{CO}_2\text{H}$. The fatal dose is 1/1500 g. per 20 g. mouse wt.

Cholesterol. A. WINDAUS. XXII. Action of benzoyl hydroperoxide on cholesterol. THEODOR WESTPHALEN. Innsbruck. *Ber.* 48, 1064-9 (1915); cf. Prileshaev, C. A. 4, 916.—A soln. of BzO_2H in CHCl_3 prepd. by Baeyer and Villiger's method from 20 g. Bz_2O_2 is heated under a reflux condenser with 10 g. cholesterol (to which, for reasons to be published later, is assigned the formula (I)) in 100 cc. CHCl_3 until the Salkowski

reaction for (I) disappears (about 6 hrs.), shaken with dil. KOH , washed with H_2O and evapd.; the resulting sirup, on treatment with petr. ether and rubbing with a glass rod, yields 5.5 g. of α -cholesterol oxide (II), slender pearly tables from AcOEt , m. $140-1^\circ$, $[\alpha]_D^{20} -37.43^\circ$ in C_6H_6 , gives a cherry-red, then violet color in the Liebermann-Burchard test; 0.5 g. in 50 cc. of 95% alc. and 2 g. digitonin in 200 cc. alc. deposit quickly and almost quant. an addition product, $\text{C}_{27}\text{H}_{48}\text{O}_2\cdot\text{C}_{24}\text{H}_{40}\text{O}_{18}$, needles from MeOH , gradually decomp. above 230° . Acetate (a), from (II) boiled 1 hr. with 10 parts Ac_2O , needles from dil. alc., m. 98° . With CrO_3 (II) yields Mauthner and Suida's oxycholestenone

and oxycholestenediol, while 10 hrs. heating at 115° with 10 parts H_2O gives α -cholestaneetriol, $\text{C}_{27}\text{H}_{48}\text{O}_3$, identical with Pickard and Yates' dehydrocholestaneetriol, to which they assign the comp. $\text{C}_{27}\text{H}_{46}\text{O}_3$ (C. A. 3, 2679). (a) in AcOH treated with a few drops of concd. H_2SO_4 gradually deposits a *cholestaneetriol diacetate* (III), m. 166° , which,

cautiously treated with Ac_2O and a few drops of H_2SO_4 , yields a *cholestenediol diacetate* (IV), leaflets from MeOH, m. 125° . With CrO_3 -AcOH, (a) gives a *cholestanonediol monoacetate*, identical with the product obtained by P. and Y. from their dehydrotriol acetate. The mother liquors from (II) gradually deposit non-homogeneous crystals, m. $100\text{--}10^{\circ}$, consisting chiefly of an isomeric β -cholesterol oxide, for they yield an acetate isomeric with (a), needles, m. 114° ; the oxide regenerated from this differs from the α -form in giving the L.-B. test with the same scale of colors as (I) itself, while with (II) the color remains at the red-violet stage. The β -oxide gives an insol. *digiloin compound*.

CHAS. A. ROUILLER.

Sulfoxyl compounds. IX. Sulfones from rongalite. A. BINZ, O. LIMPACH and W. JANSSEN. Berlin. *Ber.* 48, 1069-77(1915); cf. C. A. 3, 176; 4, 3221.—*p,p'*-Tetramethyldiaminodibenzyl sulfone (a) (formerly assigned the structure $\text{Me}_2\text{NC}_6\text{H}_4\text{CH}_2\text{SO}_2\text{C}_6\text{H}_4\text{NMe}_2$), needles, m. 198° , is obtained in 45 g. yield from 70 g. rongalite, 32 cc. com. HCHO, 100 g. PhNMe_2 , 42 cc. concd. HCl and 100 cc. H_2O heated 3 hrs. on the H_2O bath. *Picrate*, $\text{C}_{18}\text{H}_{14}\text{O}_8\text{N}_2\text{S}_2\text{C}_6\text{H}_4(\text{NO}_2)_2\text{OH}$, yellow crystals, m. 170° . *Dimethosulfate*, $\text{C}_{22}\text{H}_{20}\text{O}_{10}\text{N}_2\text{S}_2$, obtained from 10 g. of the sulfone heated 6 hrs. with 42 g. Me_2SO_4 in 120 cc. CHCl_3 , scales from alc., m. 259° . *Dinitro derivative*, $[\text{O}_2\text{N}(\text{Me}_2\text{N})\text{C}_6\text{H}_4\text{CH}_2]_2\text{SO}_2$, obtained in 3 g. yield [probably a misprint for 30 g., as the crude product, containing some of the mono- NO_2 deriv., weighed 34 g.—ABSTR.] from 33.2 g. (a) in 150 cc. concd. H_2SO_4 introduced in the course of 25 min. into 36 g. concd. HNO_3 and 55 g. H_2SO_4 and allowed to stand 12 hrs., yellow-brown needles from AcOH, m. 191° (that each NO_2 group has entered a different ring is arbitrarily assumed); 3.8 g. heated on the H_2O bath with 20 cc. concd. HCl and 6.5 g. Sn gives 1 g. *tetramethyltetraaminodibenzyl sulfone*, needles from alc., m. 184° . *Monochloro-p,p'*-tetramethyldiaminodibenzyl sulfone, from 4.8 g. (a) allowed to stand overnight in 4.2 cc. concd. HCl and 3 cc. of 30% H_2O_2 , needles from alc., m. $162\text{--}4^{\circ}$. *p,p'*-Tetraethyl-diaminodibenzyl sulfone (b), obtained in 11.5 g. yield from 36 g. rongalite, 16 cc. HCHO, 45 g. PhNEt_2 , 31.5 cc. HCl and 48 cc. H_2O heated 8 hrs., leaflets from alc., m. $162\text{--}3^{\circ}$; with HCl and H_2O_2 , it forms, unlike (a), a *dichloro derivative*, needles from alc., m. $97\text{--}8^{\circ}$ (yield, 2 g. from 3.4 g. (b)). *p,p'*-Diaminodibenzyl sulfone, in 50 g. yield from 35 g. rongalite, 16 cc. HCl, 37 g. PhNH_2 and 100 cc. H_2O at 60° and subsequent warming with 60 cc. dil. HCl, non-crystallizable; *diacetyl derivative*, small crystals from AcOH, m. 281° . *p,p'*-Diaminodi-*o*-tolyl sulfone, in 49 g. yield from 35 g. rongalite and 43 g. *o*- $\text{MeC}_6\text{H}_4\text{NH}_2$; *diacetyl derivative*, silky needles from AcOH, m. 274° . *p,p'*-Diaminodiansyl sulfone, in 11 g. yield from 7 g. rongalite, 3.2 cc. HCHO, 9.2 cc. HCl, 9.8 g. *o*- $\text{MeOC}_6\text{H}_4\text{NH}_2$, and 30 cc. H_2O on the H_2O bath, faintly yellow-green prisms from C_6H_6 , m. $184\text{--}5^{\circ}$, easily sol. in dil. acids. From 15 g. (a) boiled with 27 g. PhNH_2 -HCl and 30 g. PhNH_2 until the evolution of SO_2 ceases (about 7 min.), freed from excess of PhNH_2 with soda and steam, extd. with Et_2O , dried with CaCl_2 and evapd., there is obtained 4.5 g. of $\text{Me}_2\text{NC}_6\text{H}_4\text{CH}_2\text{C}_6\text{H}_4\text{NH}_2$, m. $90\text{--}1^{\circ}$ (Cohn and Fischer, *Ber.* 33, 2590 (1900)), which with BzH in hot alc. gives *benzylidenedimethyldiaminodiphenylmethane*, faintly yellow needles from alc., m. 90° . 3,4-Me(H_2N) $\text{C}_6\text{H}_3\text{CH}_2\text{C}_6\text{H}_4\text{NMe}_2$,

m. 93-4°, is similarly obtained in 57 g. yield from 40 g. (a) and 45 g. *o*-MeC₆H₄NH₂.HCl heated 15 min. with 40 g. Pb(OAc)₂. 3,4-Me(H₂N)C₆H₃CH₂C₆H₄NEt₃, m. 59-60° (Meister Lucius and Brüning, *Ger. pat.* 107,718), is obtained in 4.5 g. yield from 8 g. (b), 6 g. *o*-MeC₆H₄NH₂.HCl, 40 cc. *o*-MeC₆H₄NH₂ and 1 g. Pb(OAc)₂ boiled 10 min. *p*-Dimethylaminophenyl- α -hydroxynaphthylmethane, from (a) and α -naphthol boiled 4.5 hrs. in cumene, flat needles from C₆H₆, m. 149°. β -Hydroxynaphthyl isomer, in 8 g. yield from 15 g. (a) heated 4.5 hrs. with 13.5 g. β -naphthol in 100 cc. cumene, m. 144-5°.

CHAS. A. ROUVILLER.

Ditertiary hydrazines. XIX. New contribution to the knowledge of bivalent nitrogen. HEINRICH WIELAND. Acad. Sci., Munich. *Ber.* 48, 1078-95(1915); cf. C. A. 8, 336.—It has previously been found that negative substituents in the C₆H₅ nuclei of tetraarylhydrazines (NO₂, Ph in PhC₆H₄ derivs., etc.) impede, while Me and MeO favor dissociation at the N. The investigation has now been extended to basic substituted tetraarylhydrazines. [In the following, R = *p*-Me₂NC₆H₄.] R₂NH (Bindschedler, *Ber.* 16, 866(1883)), which is colorless when perfectly pure and m. 121°, is best obtained by alternately introducing, in small portions at a time, 150 g. *p*-ONC₆H₄-NMe₂.HCl (in 400 cc. H₂O at 60-70°) and about 400 g. Zn dust into 1 l. of 30% HCl (toward the end of the reaction concd. HCl must be added, so that an excess of acid is always present); the almost colorless soln. is filtered hot, cooled, treated with 96 g. PhNMe₂, then, drop by drop, with a concd. soln. of 83 g. Na₂Cr₂O₇; 220-50 g. of the dye seps. in green leaflets which, however, are much more sol. in H₂O than, and lack the Cu luster of, the compd. described by B., but, on standing and especially on rubbing, the concd. aq. soln. quickly deposits the red double salt (found Cl, 19.79%; calcd., 19.86%); both salts show the same color in soln. and the green form is either an acid salt or a 2nd modification of the normal Zn double salt. A fresh satd. aq. soln. of 200 g. of the dye at 40° is poured through a folded filter into 200 g. Na₂S₂O₄ in 500 cc. of 20% NaOH, 500 cc. NH₄OH and 1 l. H₂O vigorously stirred or turbined and the pptd. red salt is dissolved by warming; the leuco base which then seps. in colorless cryst. flocks is pressed out, washed free of alkali with cold H₂O, dried on clay *in vacuo* over H₂SO₄ and KOH and recrystd. from much ligroin. It now forms gleaming, often perfectly colorless leaflets (yield, 120 g.). From 5 g. of this in 6 cc. C₃H₅N and 20 cc. Et₂O, shaken 2 hrs. at -15° with 3 g. ignited Na₂SO₄ and 1 g. Ag₂O (1 and 1.8 g. more Ag₂O being added at the end of 0.5 and 1 hr., resp.), drained, washed with cold Et₂O until almost colorless (care being taken that too much (moist) air is not drawn through the ppt.), is obtained 4 g. tetra-(*p*-dimethylamino)tetraphenylhydrazine (a), (R₂N—)₂ (still containing some Ag and Na₂SO₄), purified by suspending in 20 cc. Et₂O, pouring off the lighter (a), filtering, digesting with 8 cc. C₆H₆, washing the insol. portion with Et₂O, treating the clear violet soln. with 10 cc. Et₂O and 5 cc. gasoline and allowing to stand well stoppered 0.5 hr. in a freezing mixt.; there is thus obtained at most 1 g. of colorless microscopic rodlets, unstable even *in vacuo* in the dark, very quickly turned blue by atm. moisture, m. 74-6° to a dark red liquid, easily sol. in C₆H₆, PhNO₂ and alc. (but with rapid alteration); the solns. of the pure (a) in C₆H₆, Et₂O, acetone and C₆H₅N are at first a pure and intense yellow, those in PhNO₂ red; the yellow solns., either in the presence or absence of air, gradually assume a red color; in sunlight the change is almost instantaneous. The dissociation of (a) into the free radicals R₂N is so great that it can be detd. by f. p. detns.; it amounts to 10% in C₆H₆ and 21% in PhNO₂. (a) adds NO instantly to form tetramethyldiaminodiphenylnitrosoamine (b), R₂NNO, and with Ph₃C to give triphenylmethyldiaminodiphenylamine (c), R₂NCPPh₃. Solns. of (a) of equal concn. in Et₂O, C₆H₆ and PhNO₂ contain no more (a) after about 50, 24 and 12 hrs., resp., the products of decompn. being R₂NH and the perazine RN(C₆H₄MeNMe₂)₂NR; at the same time another reaction takes place

to a small extent, accompanied by the appearance of a red color (see above), due to decompn. into Me and trimethylindamine (methyltrimethylaminophenylquinonediimine) (*d*), $\text{MeN}:\text{C}_6\text{H}_4:\text{NR}$ (what becomes of the Me has not been detd.). (*d*) is also obtained by oxidizing (*a*) with Ag_2O . With H_2O (*a*) gives R_2NH and the imonium base $\text{HONMe}_2:\text{C}_6\text{H}_4:\text{NR}$ which quickly (immediately in the presence of alkalis) decomp. into $\text{O}:\text{C}_6\text{H}_4:\text{NR}$ and NHMe_2 , the distinct green color given by all (*a*) solns. on addition of H_2O and the instantaneous change to blue produced by alkalis affording a very sharp test for (*a*). That it is the radical R_2N , not (*a*), that reacts in these cases is shown by dilg. equal vols. of a C_6H_4 soln. of (*a*) with 5 vols. petr. ether and C_6H_6 , resp.; the former becomes practically colorless while the latter is unchanged, and on shaking with H_2O , the former imparts no color to the H_2O while the latter turns it a deep green. Contrary to all tetraarylhydrazines previously studied, (*a*) dissolves in dil. acids, to be sure, but without color, and even in anhydrous acids (HCl in Et_2O , glacial AcOH) forms the normal colorless salts, the salt formation resulting in a great strengthening of the N.N union in (*a*); the salts no longer dissociate like the free (*a*) and the N.N union is destroyed by reducing agents only with difficulty; even a double SnCl_4 salt can be obtained and long treatment with Zn dust in HCl is necessary to split the salt into 2 mols. (with the free (*a*) Pd black and H in Et_2O effect this cleavage instantaneously). If, in the prepn. of (*a*) from R_2NH and Ag_2O in Et_2O , no $\text{C}_6\text{H}_5\text{N}$ (which so increases the oxidizing power of the Ag_2O that the reaction can be carried out at a low temp.) is used, the (*a*) cannot be isolated from the oxidized soln., the only cryst. product ever obtained being (*d*). By passing in NO, however, (*b*) is obtained in 60% yield; it seps. from alc. in fiery yellow needles, begins to decomp. 148° , m. 155° , is not appreciably changed by boiling xylene, is smoothly decompd. into NH_3 and R_2NH by SnCl_4 . It can be obtained directly from R_2NH in cold concd. AcOH soln. with a slight excess of NaNO_2 . PbO_2 , HgO and other oxidizing and dehydrating agents also easily attack R_2NH ; $\text{NH}_3\text{-AgNO}_3$ is at once reduced; Pd black with or without O and quinone instantly redden its colorless Et_2O soln., light accelerating the oxidation extraordinarily; strangely, however, H_2O_2 in Et_2O reacts only slowly. (*c*), obtained almost quant. from (*a*) and Ph_3C in C_6H_6 and crystd. from $\text{C}_6\text{H}_6\text{-EtOH}$, begins to redden 120° , m. 157° , momentarily dissolves in dil. HCl but at once deposits Ph_3COH , dissolves in concd. H_2SO_4 with the yellow color of Ph_3COH and is decolorized by H_2O ; its C_6H_6 and xylene solns. become intensely red after a few hrs. in the cold, at once on heating, with formation of (*d*); light accelerates the change, which, however, is independent of atm. O.

CHAS. A. ROUILLER.

Best method of preparing phenol blue. GUSTAV HELLER. Univ. Leipzig. *Ber.* 48, 1288-9(1915).—Referring to Wieland's statement (preceding abstr.) that absolutely pure phenol blue m. 162° and is best prepd. from Bindschedler's green with alkalis by Möhlman's method (*Ber.* 16, 2855(1883)), (H. points out that this method also is not free from objectionable features, as the dye with hot alkalis again splits off NHMe_2 with formation of a red color, so that even in the cold this reaction cannot be wholly excluded). Subsequent crystn. from ligroin naturally purifies the product. A product m. 167° after crystn. can be obtained by the Gnehm method with perfectly pure reagents (*J. prakt. Chem.* 69, 162(1904)). $p\text{-H}_2\text{NC}_6\text{H}_4\text{NMe}_2$ can be obtained by reduction of aq. $\text{ONC}_6\text{H}_4\text{NMe}_2\text{HCl}$ with Zn dust at 40° without addition of acid; this is a com. method of prepn.

CHAS. A. ROUILLER.

Some notes on triphenylmethyl. HEINRICH WIELAND. *Ber.* 48, 1096-7(1915).—By using ligroin instead of C_6H_6 in the Schmidlin-Schlenk method, C_6Ph_3 is obtained in 60% yield without the tedious evapn. of the solvent; 10 g. Ph_3CCl in the Schmidlin app. in an ordinary distg. flask is boiled under a reflux condenser in 60 cc. ligroin (b. $70\text{-}90^\circ$) with 20 g. Cu bronze in a CO_2 atm. for 45 min., filtered into a distg. flask filled

with CO_2 , and the stoppered flask is cooled in ice 0.5 hr. and then in a freezing mixt. The C_2Ph_4 seps. in faintly yellow rosetts; the side tube of the distg. flask is connected with a CO_2 generator (the connecting rubber tube being filled with Et_2O to displace the air), the ligroin slowly poured off through the top of the flask and replaced by 0.5 its vol. of Et_2O ; the crystals are loosened with a Cu wire, mashed with a broad glass rod, transferred to a filter plate, washed with CO_2 and placed *in vacuo*; so prepd., it is free from detectable amts. of peroxide and dissolves clear in C_6H_6 . C. A. R.

Intermediate occurrence of free radicals in chemical reactions. Decomposition of aromatic hydrazo compounds. HEINRICH WIELAND. Acad. Sci. Munich. *Ber.* 48, 1098-1112 (1915); cf. Stieglitz and Curme, *C. A.* 7, 2397; Curme, *C. A.* 7, 3509. —W. believes that S. and C.'s kinetic measurements agree fully as well with his theory of the decompn. of $(\text{PhNH})_2$, *vis.*: $(\text{PhNH})_2 \longrightarrow (\text{PhN}\cdot)_2 + 2\text{H}$, $(\text{PhNH})_2 + 2\text{H} \longrightarrow 2\text{PhNH}_2$, the 1st reaction being measurably slow, the 2nd immeasurably fast, as with their theory: $(\text{PhNH})_2 \longrightarrow \text{PhN} + \text{H}_2\text{NPh}$, $2\text{PhN} \longrightarrow (\text{PhN}\cdot)_2$ (cf. W., *C. A.* 6, 1296, where with Pd black as catalyst of the 1st stage of the reaction he obtained H at low temps.). A possible method of deciding the question by chem. means is the following: If, instead of $(\text{PhNH})_2$, a non-sym. hydrazo compd. XNHNHY (in which X and Y are different aromatic residues) is used, from S. and C.'s theory it would be expected that the 2 possible bases XNH_2 and YNH_2 would not be formed in equimol. amts., and, moreover, that all 3 of the possible azo compds. $(\text{XN}\cdot)_2$, $(\text{YN}\cdot)_2$ and $\text{XN}\cdot\text{NY}\cdot$, would be formed, while W.'s theory calls for the formation of equimol. amts. of XNH_2 and YNH_2 on the one hand and of $\text{XN}\cdot\text{NY}\cdot$ only on the other. The exptl. facts agree with W.'s views. When 0.708 g. *p*- $\text{MeC}_6\text{H}_4\text{NHNHPh}$ in 20 cc. alc. is heated 12 hrs. at 132° , then dild. with alc. to 50 cc., the unchanged hydrazo compd. oxidized with alc. I, the soln. acidified with H_2SO_4 , the I and azo compd. removed with steam, the soln. made alk., the bases distd. off into HCl (there always remains a small tarry residue with isonitrile-like odor), the distillate treated with 200 cc. concd. HCl, evapd. almost to dryness, made alk. with concd. NaOH, the bases extd. with Et_2O , dried with K_2CO_3 , pptd. in Et_2O as the acid oxalates, then dried *in vacuo* and weighed or titrated with 0.1 N KOH, and finally titrated with Br by C.'s method, it is found that they consist, within 2-3%, of an equimol. mixt. of $\text{MeC}_6\text{H}_4\text{NH}_2$ and PhNH_2 ; the error of C., who found 68 and 32%, resp., of the 2 compds., was due to the fact that he did not take into consideration the by-product formed by rearrangement; he detd. by titration with I the extent of the reaction and assumed that the amt. of I used corresponded by difference to the amt. of bases formed, without taking into account the semidine formed, whereas W. detd. the amt. of bases really formed by pptg. them with $(\text{CO}_2\text{H})_2$, control expts. having shown that while a small amt. of the 2 oxalates remain in soln. in Et_2O , the solubility of each is nearly the same. The steam distillate containing the azo compd., when freed from I with NaHSO_3 , yields light yellow-brown leaflets, m. 69.5° , and, after a 2nd steam distn., m. 70° sharply, showing that only $\text{MeC}_6\text{H}_4\text{N}\cdot\text{NPh}$ is present, since a mixt. of 0.1 g. $\text{MeC}_6\text{H}_4\text{N}\cdot\text{NPh}$ and 0.01 g. $(\text{PhN}\cdot)_2$, distd. with steam gave a product sintering 54° , m. 64° . *p*-Methoxy-*p*-methylazobenzene, from 6 g. *p*- $\text{MeC}_6\text{H}_4\text{NO}$ and 6 g. *p*- $\text{MeOC}_6\text{H}_4\text{NH}_2$ boiled 30 min. with 3 cc. AcOH in 25 cc. alc., orange-yellow prisms from alc., softens 104° , m. $110-1^\circ$, slowly volatile with steam (about 0.1 g. per l.), reduced after a few min. boiling in alc. with concd. aq. NH_3 and Zn dust to the hydrazo compound, needles, sinters and turns yellow 85° , m. 95° , soon turns yellow in the air, is very sensitive to light, both in the solid state and in soln., the autooxidation being markedly accelerated by acids, the colorless compd. dissolving in AcOH with yellow color and addition of a few drops of dil. HCl to an aq. suspension at once producing a deep red-violet color, due to oxidation of the semidine formed by rearrangement. From 3.85 g. heated 12.5 hrs. at 144° in alc. is obtained 0.933 g. of

the azo compd. (steam distn. yielded 0.17 g. with practically the same m. p.) and equimol. amts. of $\text{MeOC}_6\text{H}_4\text{NH}_2$ and $\text{MeC}_6\text{H}_4\text{NH}_2$. *p*-Methyl-*p*-chloroazobenzene, from $\text{MeC}_6\text{H}_4\text{NO}$ and $\text{ClC}_6\text{H}_4\text{NH}_2$, orange-yellow leaves, softens 149° , m. 153° , apparently identical with the compd. m. $149-50^\circ$, obtained by Paganini, *Ber.* 24, 365(1891), from $\text{MeC}_6\text{H}_4\text{N}:\text{NC}_6\text{H}_4\text{OH}$ and PCl_5 . *Hydrazo compound*, needles, m. 124° , becoming faintly yellow, reddens about 150° , more stable towards atm. O than the preceding hydrazo compd.; 3 g. heated 12.5 hrs. at 144° in 25 cc. alc. gives, besides a semidine yielding a blue dye by some change not studied, 0.846 g. of the azo compd. and equimol. amts. of $\text{ClC}_6\text{H}_4\text{NH}_2$ and $\text{MeC}_6\text{H}_4\text{NH}_2$. *p*- $\text{EtO}_2\text{CC}_6\text{H}_4\text{NHNHPh}$ similarly yields only $\text{EtO}_2\text{CC}_6\text{H}_4\text{N}:\text{NPh}$ when heated 14 hrs. in xylene at $160-70^\circ$ (no method could be devised for detg. the relative amts. of the bases formed). CHAS. A. ROUILLER.

Aromatic hydrazines. XX. Dissociation of triphenylhydrazine. HEINRICH WIELAND AND ARNO REVERDY. *Acad. Sci., Munich. Ber.* 48, 1112-6(1915).—Thus far, only ditertiary hydrazines were known to dissociate into free radicals (see preceding abstr. for the proof that $(\text{PhNH})_2$ does not). When, however, 2 g. Ph_2NNHPh is boiled 2 hrs. in 15 cc. xylene (a weak current of CO_2 being passed through the boiling soln.), the soln. gradually darkens and finally becomes red-brown; steam distn. now gives $(\text{PhN})_2$, PhNH_2 and Ph_2NH . The remaining product is *p*- $\text{PhN}:\text{C}_6\text{H}_4:\text{NPh}_2$ (a); for its identification the freshly boiled xylene soln. (before the steam distn.) is dild. with Et_2O , extd. with 0.2 *N* HCl as long as appreciable amts. of the red-violet dye are removed, the combined exts. treated with fresh Et_2O (which, owing to slight hydrolysis of the salt, removes a little of the red-brown base) and the dye is salted out in bronzy flocks with NaCl. W. and A. consider this evidence that the Ph_2NNHPh dissociates into Ph_2NH and PhN , the latter free radical polymerizing to $(\text{PhN})_2$, while another portion, combining with unchanged Ph_2NNHPh , gives $\text{Ph}_2\text{NNHC}_6\text{H}_4\text{NHPh}$, this leuco compd. losing the labile H to form (a), while the H itself with the Ph_2NNHPh gives Ph_2NH and PhNH_2 . In the same way are obtained PhNH_2 , $(\text{PhN})_2$, $(\text{MeC}_6\text{H}_4)_2\text{NH}$ and a violet-red dye (reduced to $\text{MeC}_6\text{H}_4\text{NHPh}$ and $(\text{MeC}_6\text{H}_4)_2\text{NH}$) upon heating in xylene *p*-ditolylphenylhydrazine, which is prepd. by treating 6.2 g. Mg shavings and 40 g. PhBr in 200 cc. Et_2O at -15° with 10 g. $(\text{MeC}_6\text{H}_4)_2\text{NNO}$ in Et_2O ; it seps. from AcOEt-EtOH in long needles (yield, 3-4 g.), begins to turn brown 120° , m. $142-3^\circ$, sol. in H_2SO_4 with yellow color, turning green on warming.

CHAS. A. ROUILLER.

The Grignard reaction with nitroso compounds. HEINRICH WIELAND AND ALEXANDER ROSEBU. *Acad. Sci., Munich. Ber.* 48, 1117-21(1915).—From the analogy in many reactions of the NO to the CO group, it might be expected to give NH_2OH derivs. with Grignard reagents: $\text{RNO} + \text{R}'\text{MgBr} \longrightarrow \text{RNR}'\text{OMgBr} \longrightarrow \text{RNR}'\text{OH}$. This can be done in some cases (cf. *C. A.* 6, 1296) but as a rule the reaction does not stop at this stage; the $\text{RNR}'\text{OMgBr}$ is reduced by a 2nd mol. of $\text{R}'\text{MgBr}$ and the O made available converts the $\text{R}'\text{MgBr}$ into $\text{R}'\text{OMgBr}$: $\text{RNR}'\text{OMgBr} + \text{R}'\text{MgBr} \longrightarrow \text{RNR}'\text{MgBr} + \text{R}'\text{OMgBr}$. From 4.7 g. Mg shavings and 35 g. *p*- $\text{MeC}_6\text{H}_4\text{Br}$ in 200 cc. Et_2O treated at -5° to -10° in the course of 1 hr. with 12 g. *p*- $\text{MeC}_6\text{H}_4\text{NO}$ and allowed to stand overnight is obtained 9 g. of *p*-ditolylhydroxylamine, reddens 80° , m. $91-2^\circ$ (decompn.), sol. in concd. H_2SO_4 with red color soon changing to green, insol. in aq. acids and alkalies. Mineral acids decomp. it in a complicated way; with HCl in Et_2O it gives, among other products, a small amt. of ditolylidihydro-tolazine (*C. A.* 3, 180); on reduction it gives $(\text{MeC}_6\text{H}_4)_2\text{NH}$ quant.; with diphenylhydrazine it condenses to a red-violet dye, but not with *p*-ditolylhydrazine; it is not stable for long, beginning to decomp. in a few days into $(\text{MeC}_6\text{H}_4)_2\text{NH}$ and a red substance, apparently of high mol. wt., sol. in alkalies with red color; oxidizing agents easily attack it. Diarylhydroxylamines cannot be obtained by the action of halogen-

benzenes on PhNHOH in the presence of Cu powder; *o*-IC₆H₄CO₂H, *e. g.*, does not give HO₂CC₆H₄NPhOH, but after 8 hrs. boiling in C₆H₆ is obtained, together with azoxybenzene, considerable *phenylanthranilic acid*, leaflets from benzene-gasoline, m. 181°, sol. in soda. Ph₂NNHPh (Busch and Hobein, *Ber.* 40, 2101(1907)) is also obtained, together with PhOH and Ph₂, from Mg, PhBr and Ph₂NNO in Et₂O at -15°. Similarly, from Mg, PhBr and nitrosocarbazole are obtained carbazole and Ph₂NH; AcNPhNO gives Ph₂NH and AcNHPh.

CHAS. A. ROULLER.

A new synthesis of aromatic ketones. I. Preparation of some phenol ketones.

KURT HOESCH. Charlottenburg. *Ber.* 48, 1122-33(1915).—Equimol. amts. of phenol and nitrile in Et₂O (with the addition of powdered ZnCl₂ when necessary) are treated for several hrs. with dry HCl, whereby the solvent is gradually driven off; after a time the residue, dissolved in cold H₂O, is freed from unchanged phenol and nitrile with Et₂O, neutralized with NH₃ and boiled 15-30 min. In this way resacetophenone is obtained in 70% yield from *m*-C₆H₄(OH)₂ and MeCN; 5 g. *m*-MeOC₆H₄OH gives 1.8 g. each of peonol and *isopeonol*, 4,2-HO(MeO)C₆H₃Ac, lancet-like needles from H₂O, non-volatile with steam, gives no color with FeCl₃, m. 138°. From 6 g. anhydrous orcinol is obtained 5 g. *orcacetophenone*, 2,4,6-Me(HO)₃C₆H₃Ac, silky needles from H₂O, m. 159°, gives a deep red color with FeCl₃ in alc. Instead of neutralizing the reaction mixt. and boiling, it is better to acidify with 30 cc. of 5 N H₂SO₄ and shake with 2 vols. of Et₂O, the intermediate *ketimide*, Me(HO)₂C₆H₃CMc:NH, sepg. as the *sulfate* in needles which, boiled 15 min. with 20 parts H₂O, give the pure ketone almost quant. The latter with 1 mol. Me₂SO₄ gives a *monomethyl ether*, m. 79°, identical with Tambor's *isoorcacetophenone* Me ether (*C. A.* 2, 1710). Owing to its unsym. arrangement corresponding to resacetophenone, orcyraldehyde and orsellinic acid, H. believes his ketone is better entitled to the name *orcacetophenone* than Rasinski's sym. ketone, 4,2,6-Me(OH)₃C₆H₃Ac (*J. prakt. Chem.* 26, 59), for which H. proposes the name *p*-orcacetophenone. From 5 g. 3,5-HO(MeO)C₆H₃Me are obtained 2.1 g. *isoacetoevernone*, 6,3,5-Ac(HO)(MeO)C₆H₃Me, quadratic tables from H₂O, m. 150°, non-volatile with steam, gives no color with FeCl₃, and 1.8 g. of *acetoevernone*, 2,3,5-Ac(HO)(MeO)-C₆H₃Me, volatile with steam, gives a deep red color with FeCl₃, m. 79°. From phloroglucinol is obtained, through the *ketimide sulfate*, slender needles, 80% of *phloracetophenone*, m. 218°, identical with Heller's "monoacetotriketohexamethylene" (*C. A.* 6, 1293; cf. also Leuchs and Sperling, *C. A.* 9, 1060). Benzoorsorcinol is obtained from *m*-C₆H₄(OH)₂ and PhCN through the *ketimide hydrochloride*. From 6 g. anhydrous orcinol and 5 g. PhCN is obtained 6.2 g. of the *ketimide hydrochloride*, yellow needles from dil. HCl (free *ketimide*, yellow prisms from AcOEt-ligroin), of *benzoorsorcinol*, 2,4,6-Me(HO)₃C₆H₃Br, tables from H₂O, m. 141°, gives an intense red-brown color with alc. FeCl₃, sol. in NaOH with red color but without change, even on long heating. *Benzo-phloroglucinol*, needles containing (in cool and not too dry air) 1 H₂O, m. 165°, sol. in 2.5 parts boiling H₂O and 310 parts at 22°, gives a brown-red color with FeCl₃, reduces Fehling and NH₃-AgNO₃ solns., produces coughing and sneezing in the dry state, sol. in alkalis with red color and decompn., after 1 hr.'s boiling, into C₆H₃(OH)₃ and BzOH. It is obtained in 65% yield through the *ketimide sulfate*, yellow prisms from dil. H₂SO₄.

C. A. R.

Acetotriketohexamethylene. GUSTAV HELLER. Univ. Leipzig. *Ber.* 48, 1286-8 (1915); cf. preceding abstr.—Comparison of Heller's product (*a*) with Hoesch's phloracetophenone (*b*) shows that the 2 compds. are indeed identical; even the m. p. of (*a*) can be raised to that of (*b*) by repeated digestion with boiling C₆H₆ before recrystn. (*a*), however, in all its reactions so far studied behaves like a triketohexamethylene deriv. but it is, of course, possible that other reactions may be discovered in which it will react like phloracetophenone.

CHAS. A. ROULLER.

Organic peracids. J. D'ANS AND A. KNEIP. *Ber.* 48, 1136-46(1915); cf. C. A. 6, 2737; C. A. 8, 923.—Basing the method of prepn. on the same principle as before, D'A. has obtained from 20 g. HCO_2H , 25 g. H_2O_2 and 6.5 g. H_2SO_4 allowed to stand 2 hrs. a 10.6 g. fraction with 89.9% HCO_2H (a) and 2.6% H_2O_2 , another of 8.6 g. with 74.9% (a) and 3.3% H_2O_2 , and a residue of 31.6 g. with 20.4% (a) and 31.2% H_2O_2 . The 90% (a) is a colorless liquid with the characteristic peracid odor, miscible with H_2O , Et_2O , EtOH , quite easily sol. in most org. solvents, more easily volatile than HCO_2H , produces painful inflammations on the skin and its vapors violently irritate the mucous membranes. After 24 and 48 hrs. at 0° , it contains only 67.5 and 60.8%, resp., of (a) and the H_2O_2 content simultaneously increases to 6 and 8%, resp. The decompn. may take place according to the equations: (1) $2(a) \longrightarrow 2\text{HCO}_2\text{H} + \text{O}_2$; (2) $(a) \longrightarrow \text{H}_2\text{O} + \text{CO}_2$; (3) $(a) + \text{H}_2\text{O} \longrightarrow \text{HCO}_2\text{H} + \text{H}_2\text{O}_2$, (2) and (3) predominating with concd. (a). (2) may be accelerated to violent explosiveness by certain catalysts, and it is probable that the spontaneous decompn. consists wholly of an isomerization of (a) into H_2CO_3 . The heat of decompn. of the reaction (2), calcd. from the heat of combustion of HCO_2H to CO_2 and H_2O and the heat of decompn. of H_2O_2 (the small negative heat of formation of (a) from HCO_2H and H_2O_2 may be neglected), is about 92 cal. per g.-mol. This great endothermic property is manifested by the fact that certain solids may produce explosions with (a). The expts. were carried out by adding a little of the solid to 2-3 drops of 60% (a) at $8-10^\circ$ in a watch glass. Graphite, purified lampblack, Si, S, I, Sb, Sn, Fe (*ferrum reductum*), Al_2O_3 , pure Cr_2O_3 , anhydrous CuSO_4 , KClO_4 , $(\text{NH}_4)_2\text{S}_2\text{O}_8$, $(\text{NH}_4\text{OH})_2\text{H}_2\text{SO}_4$, boryl phosphate, CS_2 , CHCl_3 , C_{10}H_8 , glycerol, PhOH , tartaric acid, BzOH , camphor, turpentine oil, starch, cellulose have no effect. Decompn. is produced by Mg (strongly, with formation of MgO), Al powder (faintly), Ni powder reduced with H (faintly at first but with increasing violence and formate formation), CaO (with hissing), Cu_2O (energetically, with formation of formate, and, in large amts., with deflagration), CuO (faintly, with formate formation), PbO_2 (strongly, finally with deflagration, and formate formation), MnO_2 (strongly), artificial MnO_2 (with deflagration but no formate formation), IrO_2 (like MnO_2), BaO_2 (with gas evolution and, in large amts., deflagration), CrO_3 (with formation of blue HCrO_4 , followed by reduction), V_2O_5 (with formation of O_3). Red P, HCHO , BzH , PhNH_2 , etc., are energetically oxidized. Deflagration is easily produced by Hg, Tl powder, colloidal Ag, Na_2O_2 , and very energetic explosion by Zn dust, PbO , Pb_2O_4 , NaN_3 . At 20° , all these reactions are markedly more energetic; with 90% (a) they are much more violent, but Zn dust and PbO still produce explosions with 45% (a). The state of subdivision and of purity of the solids also has a marked influence. Most of these reactions are probably due to oxidation of the solid with resulting local heating; substances like Ag, MnO_2 , V_2O_5 , etc., seem to act purely catalytically. 80% (a) explodes on heating to $80-5^\circ$. While pure Fe and Si powder have no action, addition of a trace of MnO_2 produces deflagration in the 1 case and a loud explosion in the other. $\text{Ac}_2\text{O}_2\text{H}$ (b) prepd. by the method formerly used may contain considerable Ac_2O_2 if the conditions are not carefully controlled. A 50% (b) practically free of Ac_2O_2 , is obtained by allowing the calcd. amt. of H_2O_2 and Ac_2O to flow into a small amt. of the (b) prepd. by the old way (the flow being so regulated that H_2O_2 is always present in slight excess) and allowing to stand 0.5 hr. Different preps. of Ac_2O react with varying ease, being apparently the less reactive the purer they are. The 50% (b) so prepd. may be kept 14 days at room temp. without change; impurities (dust, etc.) accelerate its decompn. Solids show none of the catalytic effects on its decompn. which they exhibit towards (a). As an oxidizing agent (b) possesses the advantages of being sol. in a whole series of solvents, of being stable and hydrolyzed only slowly in H_2O and of giving a product (AcOH) which, in most cases, is not harmful.

It smoothly oxidizes aldehydes (HCHO, enanthole, BzH, anisaldehyde, *o*-NCSC₆H₄CHO) to the acids (*p*-HOC₆H₄CHO gives quinol (or quinhedrone and quinone) and HCO₂H). Amines yield the nitros and azoxy compds.; *e. g.*, 3 g. PhNH₂ in 100 cc. cold H₂O and 16.5 g. NaHCO₃ slowly treated with 12.5 g. of 41% (b) in 30 cc. H₂O and allowed to stand 12 hrs. gave 1.7 g. PhNO and 1.1 g. Ph₂N₂O; if the (b) is added quickly the yields are 2.4 and 0.75 g., resp. Similar results were obtained with *p*-MeC₆H₄NH₂, *m*- and *p*-O₂NC₆H₄NH₂ and *o*-H₂NC₆H₄CO₂H. That the azoxy compds. result from the oxidation of azo compds. first formed was confirmed by expt., (PhN:)₂, (*p*-MeC₆H₄N:)₂ and (*m*- and *p*-O₂NC₆H₄N:)₂ giving the corresponding azoxy compds. in practically quant. yield.

CHAS. A. ROUILLER.

A new dibromophenanthrene. Bromination of phenanthrene in glacial acetic acid. HÅKAN SANDQVIST. Univ. Upsala. *Ber.* 48, 1146-9(1915).—When 50 g. Kahlbaum "phenanthrene," m. 95-6°, in 700 cc. glacial AcOH is treated at room temp. with 90 g. Br, drop by drop, filtered after some hrs. from the finely cryst. dibromide and the dibromofluorene, m. 163°, which seps. after the dibromide in leaves, the mother liquor treated with 50 g. more phenanthrene in 300 cc. luke-warm AcOH, again brominated with 75 g. Br and the process repeated 8 times with decreasing amts. of fresh AcOH (300 to 70 cc.) and of Br (90 to 60 g.), 500 g. phenanthrene, 1800 cc. AcOH and 680 g. Br in all being used, there is obtained a good yield of dibromide, yielding 520 g. crude 10-bromophenanthrene on heating; moreover, there are also obtained 87 g. of the dibromofluorene and Hayduck's dark red-brown oil (*Ann.* 167, 182(1873)), which has the comp. of a monobromophenanthrene and yields a mixt. of quinones on oxidation. The AcOH mother liquors after several months deposit a solid, sepd. by crystn. from C₆H₆ into a more sol., very viscous, light red-brown oil having the comp. of a dibromophenanthrene and giving a mixt. of quinones on oxidation, and a few g. of a less sol. 10,7-dibromophenanthrene (a), colorless needles, m. 123°; it is dimorphous, for when the melt solidifies at room temp. and is then placed in a bath at 106° it remelts, but if it is reheated slowly it again m. only at 123°. Fused with KOH at 250°, it forms a Br-free, phenol-like compd.; boiled several hrs. with alc. NH₃ and Zn dust, it yields phenanthrene; it forms no picrate in alc. or C₆H₆; boiled 5-10 min. with CrO₃ in AcOH, it gives 1(or 4)-bromophenanthraquinone (b), golden yellow felted, broad needles or long leaves with metallic luster, m. 233-4°; mono $\ddot{o}$ xime, mosaic, gold-like leaves, m. 213° (decompn.). The formation of (b) shows that 1 of the Br atoms in (a) is in the "bridge" (position 9 or 10). As to the Br in (b), it cannot be in position 2 or 3, for the 2- and 3-Br compds. are known (Schmidt, *Ber.* 37, 3558, 3571) and are different from (b). The same is true of Werner's isomer (*Ann.* 322, 170). If, therefore, one Br atom in (a) is assigned position 10, the other must be at 1, 4, 5 or 8.

CHAS. A. ROUILLER.

***m*-Nitroisothiocyanobenzene and related compounds.** FR. FICHTER AND RUDOLF SCHONLAU. Basel. *Ber.* 48, 1150-4(1915); cf. *C. A.* 6, 757.—*m*-Nitroisothiocyanobenzene, O₂NC₆H₄NCS, prepd. from O₂NC₆H₄NH₂ by the Sandmeyer reaction and purified (but with some decompn.) by distg. *in vacuo* or distg. with steam and salting out with NaCl, felted needles from petr. ether, m. 56°, b₁₈ 180°. When 4.5 g. in 50 cc. of 7 *N* alc. HCl is reduced at a Pb cathode with a current d. 0.044-0.066 amp./sq. cm., and at least twice the amt. of current calcd. for the reaction O₂NC₆H₄NCS + 8H = H₂NC₆H₄SH + 2H₂O + HCN and the filtered soln. is allowed to stand a few days or is oxidized with FeCl₃, (*m*-HCl.H₂NC₆H₄S)₂ is deposited. The same result is obtained with Cu cathodes if the acid concn., current d. and excess of current are sufficiently large, but in only 2 *N* alc. HCl with 0.044 amp./sq. cm., *m*-isothiocyanoazoxybenzene is obtained in yellow flocks, sepg. from alc. in yellow felted needles, m. 96°, slowly gives a red-violet color in concd. H₂SO₄. The explanation previously advanced for the for-

mation of μ -aminobenzothiazole (*a*) in the reduction of o -O₂NC₆H₄NCS at a Pb cathode, viz., that H₂NC₆H₄SH and HCN are first formed and then condense to (*a*) + H₂, is contrary to Hofmann's observation that H₂NC₆H₄SH and HCN give benzothiazole (*b*) + NH₃ (*Ber.* 13, 1238(1880)), but it has now been found that (*o*-H₂NC₆H₄S)₂ and HCN do give (*a*), together with a little (*b*), in the presence of acids, so that in the electrolytic reduction at a Pb cathode the H₂NC₆H₄SH first formed is oxidized, under the influence of unchanged O₂NC₆H₄NCS or its intermediate reduction product, ONC₆H₄NCS, to the disulfide which, with the HCN also first formed, gives (*a*), the acidity of the electrolyte favoring this condensation while it impedes the formation of (*b*) from the mercaptan, as found by expt. The electrolytic oxidation of NCS to SO₂H compds. (*C. A.* 6, 2609) has been extended to MeNCS and CH₃(NCS)₂, but while the resulting acids are remarkably stable towards chem. oxidizing agents (HNO₃, Cl, CrO₃, KMnO₄) they are attacked at a Pt anode and partially decompd. under the conditions of their prepn. With aromatic compds. (PhNCS and *o*-O₂NC₆H₄NCS) the nucleus also is attacked and resinous products are formed. From 7.3 g. MeNCS in 150 cc. of 50% AcOH and 20 cc. concd. HCl at 30–40° with a Pt gauze anode and the calcd. amt. of current is obtained 70% MeSO₂H; CH₃(NCS)₂ similarly gives 50% CH₃(SO₂H)₂.

CHAS. A. ROUILLER.

Methylation of glucosaminic acid (a way from sugar to betaine). HANS PRINGSHEIM. Univ. Berlin. *Ber.* 48, 1158–61(1915).—From 6.5 g. glucosaminic acid (*a*) in 500 cc. H₂O, 28 g. Ba(OH)₂ and 18 g. Me₂SO₄ warmed several hrs. on the H₂O bath, filtered from the small amt. of BaSO₄ formed, decolorized with charcoal, made faintly acid with HCl, boiled with 22 g. BaCl₂ until the (MeSO₄)₂Ba is completely hydrolyzed (several hrs.), filtered, freed quant. from Ba with H₂SO₄, again decolorized with charcoal, concd. *in vacuo* at 50° and finally over H₂SO₄, dried on clay and crystd. from AcOEt-EtOH, is obtained 1 g. betaine-HCl. The other product is a non-crystallizable syrup (tetrose), which reduces Fehling soln. but forms no osazone. The transformation is interesting physiologically in showing one way in which the organism, starting from sugar, may form betaine.

CHAS. A. ROUILLER.

The iodosuccinic acids. A. WESTERLUND. Lund. *Ber.* 48, 1179–83(1915); cf. Holmberg, *C. A.* 8, 1576.—From 4.1 g. *dl*-bromosuccinic acid and 3.1 g. NaI in 70 g. acetone NaBr slowly begins to sep.; it is filtered off the next day and the acetone evapd. at room temp.; the red-brown cryst. residue (5.4 g. after drying over H₂SO₄), after soln. in H₂O, extn. with Et₂O and crystn. from C₆H₅-AcOEt, gives *dl*-iodosuccinic acid (*a*), voluminous mass, m. 135–40°, yields with Pb(OAc)₂ an amorphous white ppt. quickly becoming yellow with formation of PbI₂ on heating alone or suspended in H₂O; on rapid neutralization with KOH and treatment with AgNO₃ (*a*) gives a yellow ppt. partly sol. in HNO₃ but leaving considerable AgI undissolved. Fresh aq. (*a*) gives no ppt. with AgNO₃ but AgI begins to sep. in a few min.; in dil. HNO₃ the same thing occurs but more slowly. Attempts to prep. the *l*-acid in the same way from the *l*-Br acid gave only the *dl*-form. It was found, however, that 1.29 g. *l*-(*a*) prepd. by H.'s method, $[\alpha]_D^{17} -76.9^\circ$, kept with 1.86 g. NaI in 20 cc. H₂O at 25°, is racemized with a velocity whose const. is 0.22. Racemization similarly occurs in acetone in the presence of NaI but not in acetone alone or acetone + I. CHAS. A. ROUILLER.

Anthranil. IX. Constitution of the acylanthranils. GUSTAV HELLER. Univ. Leipzig. *Ber.* 48, 1183–95(1915).—H. shows in this paper that all acylanthranils have the structure C₆H₄.CO.NCOR (*a*), not the metoxazone form, C₆H₄.CO.O.CR:N (*b*).

Benzoylanthranil in 60 parts alc. and 2 parts of 50% N₂H₄.H₂O give 0.9 part 3-phenyl-3-hydrazino-3,4-dihydrobenzoxazone, C₆H₄.CO.O.CPh(NHNH₂).NH (*c*),

needles from AcOEt, m. 187–8° (gas evolution) (from alc. it also seps. in needles which, however, m. 4° higher; on standing the m. p. slowly falls), reduces hot Fehling soln.; 0.5 g., heated on the H₂O bath with 5 g. H₂O and 10 g. of 7% NaOH until just dissolved and at once cooled, seps. unchanged on treatment with AcOH or CO₂, while on heating with dil. HCl it dissolves and after a time *o*-BzNHC₆H₄CO₂H seps.; the reaction is more smoothly effected by rubbing with fuming HCl and allowing to stand 24 hrs. Treated in 100 parts H₂O with concd. HCl until dissolved, cooled with ice and treated with NaNO₂, (c) gives the *3-asido derivative*, needles from alc., m. 111–2° (foaming), yields BzNHC₆H₄CO₂H with hot dil. NaOH. (c) heated 15 min. in 15 parts of 60% AcOH on the H₂O bath and slowly poured into H₂O, also when heated with dil. NaOH, gives *2-phenyl-3-amino-4-quinazolone*, C₆H₄.CO.N(NH₂).CPh:N, needles from C₆H₆, m.

178–9°, easily sol. in dil. HCl. If the structure (b) for benzoylanthranil were correct, the formation of (c) would involve the direct addition of N₂H₄.H₂O to a —N:CR— group, a reaction thus far unknown (quinaldine in alc. is not attacked even on long boiling by N₂H₄.H₂O, while PhCH:NPh and *o*-O₂NC₆H₄CH:NPh give (PhCH:N)₂ and O₂NC₆H₄:NNH₂, resp., in the cold), and moreover a lactone like (b) would be expected to give a hydrazide (cf. Wedel, *Ber.* 33, 766(1900)). On the other hand, the formation of (c) from a compd. of the structure (a) is easily explained thus: (a) + N₂H₄ → C₆H₄.CO.NCR(OH)NHNH₂ → C₆H₄(CO₂H)NHCR(OH)NHNH₂ →

(c). In the same way acetanthranil and N₂H₄.H₂O give *3-methyl-3-hydrazino-3,4-dihydrobenzoxazone*, needles, m. 148° (gas evolution), reduces hot Fehling soln., sol. in dil. NaOH and repptd. by AcOH, rearranges on heating with AcOH into *3-methyl-3-amino-4-quinazolone*. CH₃(NHC₆H₄CO₂H)₂ prepd. by v. Pollack's method (*Monatsh.* 26, 327(1905)) must be purified by stirring with aq. NaOAc, filtering and pptg. hot with AcOH; it can be obtained pure, however, by dropping 4.8 g. CH₃(COCl)₂ into 19 g. *o*-H₂NC₆H₄CO₂H in Et₂O, allowing to stand several hrs., stirring with H₂O and filtering; heated with 15 parts Ac₂O until dissolved it gives 55% of *malonylbisanthranil*, yellow needles from AcOEt, begins to sinter 239°, darkens and m. about 242° (gas evolution), reconverted into the acid slowly by hot dil. H₂SO₄ or soda, quickly by dil. NaOH; with N₂H₄.H₂O it gives *3-methylenebis-[3-hydrazino-3,4-dihydrobenzoxazone]* (d), cannot be recrystd. without change, easily sol. in dil. HCl, sinters about 170°, gradually turns red-brown above 230°, does not m. 295°, soon dissolves in NaOH at room temp. and on standing deposits a violet dye sol. in H₂SO₄ with crimson color; soda dissolves (d) with red color quite rapidly at 60°, dil. NH₄OH in about 2 hrs. at room temp.; Fehling soln. is reduced on heating. When heated until just dissolved with 40 parts H₂O and 1 part soda and acidified with AcOH, (d) is not recovered unchanged but gives *malonylbisanthranilic acid bishydrazone*, [HO₂CC₆H₄NHC(:NNH₂)₂CH₂]₂, fine granules (also seps. from 96% alc. as a faintly reddish cryst. powder mixed with granules), gradually darkens above 250°, m. about 295° (faint gas evolution), quite easily sol. in dil. soda at room temp., reduces hot Fehling soln., easily dissolves in 0.1 N alkali and quickly seps. again on addition of the equiv. amt. of acid. Heated with 50% AcOH it rearranges into *methylene-2-bis-[3-amino-4-quinazolone]*, faintly yellow felted needles from PhNO₂, sol. in dil. acids but not in alkalis, gradually darkens above 250°, does not m. 300°. Oxalylbisanthranil, from (CONHC₆H₄CO₂H)₂ and 30 parts hot Ac₂O or, in 9.5 g. yield, from 10.3 g. H₂NC₆H₄CO₂H in 50 g. cold C₆H₅N and 4.8 g. (COCl)₂, allowed to stand several hrs., m. 350°, sol. in hot dil. NaOH, slowly in soda, with formation of the acid; with N₂H₄.H₂O it gives *3-bis-[3-hydrazino-3,4-dihydrobenzoxazone]*, cannot be recrystd., m. 219–20° (foaming), difficultly sol. in alkalis and mineral acids, reduces hot Fehling soln.; treated in 40 parts H₂O at 70° with NaOH until dissolved, cooled, filtered and acidified with AcOH, it gives on long standing

oxalylbisanthranilic acid bishydrazone, lancet-shaped, faintly lemon-yellow needles from 500 parts of 96% alc., m. 177–8°, sol. in dil. soda. CHAS. A. ROULLER.

Unsaturated hydroaromatic hydrocarbons. K. v. AUWERS and W. TREPPMANN. *Marburg. Ber.* 48, 1207–25 (1915).—In accordance with Wallach's rule that satd. hydroaromatic alcs. on loss of H₂O yield exclusively or chiefly hydrocarbons with an endocyclic double bond, 1-benzylcyclohexanol should give 1-benzylcyclohexene (a). That this is the case has been assumed, but not proved, by Sabatier and Mailhe (*Compt. rend.* 138, 1323 (1904)) and by Klages and Friedemann (F., *Diss. Heidelberg*, 1907), while S. and M. thought they obtained from phenylcyclohexylcarbinol the isomeric benzylidenecyclohexene (b). A. and T. have dehydrated the 2 alcs. with KHSO₄ (the C₆H₁₁CPhOH with (CO₂H)₂ and P₂O₅ also) and a comparison of their data and those of the other investigators indicate that all the products are identical, and, from spectrochem. and chem. evidence, A. and T. conclude that they are (a). 1-Phenylcyclohexanol, b₁₄ 141–4°, m. 61°, heated 0.5 hr. at 150–60° with an equal wt. of KHSO₄ gave 1-phenylcyclohexene (cf. F., and also Bauer, C. A. 8, 3181), 2 samples of which showed the following consts., resp.: b₁₇ 133°, b₁₈ 126–7°; d₄²⁰ 0.985, 0.988; n_D 1.56612, 1.56636; n_D 1.57157, 1.57180; n_B 1.58679, 1.58725, n_γ 1.60026, 1.60093 (at 14.2° for the 1st and 14.7° for the 2nd prepn.); n_D²⁰ 1.5690, 1.5694; av. E_Z, 0.65 for M_α, 0.68 for M_β, 33% for M_β—M_α, 36% for M_γ—M_α (the corresponding E_Z values for the analogously constituted α-methylstyrene are 0.62, 0.68, 31%, 32%); with KMnO₄ in aq. acetone it gives δ-benzoylvaleric acid, m. 77–8°, whose semicarbazone m. 187° (B. gives 183°); *p*-nitrophenylhydrazone, yellow needles from alc., m. 187°. 1-Benzylcyclohexanol, m. 57.5–8.5°, is obtained pure by dropping 12.7 g. PhCH₂Cl and 25 g. Et₂O into 2.4 g. Mg shavings covered with Et₂O, slowly adding the resulting mixt. to 8. g. cyclohexanone in 2 vols. Et₂O, heating about 10 min. on the H₂O bath to complete the reaction and decomp. with ice-cold NH₄Cl soln. Heated 1 hr. with 1.5 parts KHSO₄ at 150–60° it gives (a), b_{11.4} 125°, d₄²⁰ 0.962, n 1.54303, 1.54769, 1.55994, 1.57070 for α, D, β and γ at 13.2°, n_D²⁰ 1.5449, E_Z 0.27, 0.28, 16%, 18% for α, D, β—α and γ—α; with KMnO₄ it gives BzOH and a substance m. 105°, extd. from the alk. soln. by Et₂O and having the comp. of the glycol HOCH.CH₂.CH₂.CH₂.C(OH)CH₂Ph. Cyclohexyl

bromide, from the alc. and PBr₃, b_{7.8} 163°, b_{8.8} 85°, d₄²⁰ 1.325, n 1.49377, 1.49677, 1.50429, 1.51058 for α, D, β and γ at 14.3°, n_D²⁰ 1.4942, E_Z 0.26, 0.27, 7%, 9% for α, D, β—α and γ—α; 10 g. in an equal vol. of Et₂O slowly dropped into 1.5 g. Mg under Et₂O, then treated with 6.5 g. BzH in an equal vol. of Et₂O, gave 70% phenylcyclohexylcarbinol, m. 50–0.5°, b₁₇ 162°. With 1.5 parts KHSO₄ 1 hr. at 150–60° it gives (a), b₁₈ 125°, d₄²⁰ 0.961, n 1.54202, 1.54651, 1.55879, 1.56939 for α, D, β and γ at 13.7°, n_D²⁰ 1.5437. The alc. heated with 1.5 parts (CO₂H)₂ under 50 mm. in CO₂ at such a temp. that the hydrocarbon distd. over gave an (a) b_m 139–41°, d₄²⁰ 0.959, n 1.54327, 1.54774, 1.56043, 1.57093 for α, D, β and γ at 14.6°, n_D²⁰ 1.5453. With 1 part P₂O₅ gradually heated to 160° is obtained an (a) b₁₈ 132–3°, d₄²⁰ 0.964, n 1.54009, 1.54426, 1.55601, 1.56577 for α, D, β and γ at 14.1°, n_D²⁰ 1.5416. Av. E_Z of the above 3 samples of (a), 0.26, 0.26, 15%, 15% for α, D, β—α and γ—α. From 15 cc. (a), 15 cc. AcOH and 11 cc. AmNO₂ in a freezing mixt. slowly treated with 6 cc. crude HCl and 6 cc. AcOH, allowed to stand 0.5 hr. in the cold and dild. with MeOH, is obtained in varying yield (52 g. from a total of 120 g. (a)) the *nitrosochloride*, quite unstable, quickly changing on the H₂O bath to a brown oil, m. 110° when placed in a bath at that temp., m. 105–7° if heated more slowly; 6 g. heated to boiling with 6 g. NaOAc and 24 cc. AcOH, treated with 1 g. H₂SO₄, cooled, neutralized and extd. with Et₂O gives the *oxime* (16 g. from 52 g. nitrosochloride), needles from MeOH, m. 136–8°, of 1-benzyl-5-cyclohexen-2-one, obtained from the oxime by boiling 1 hr. with 30% H₂SO₄ (8 g. from 16 g. oxime); it

b_{118} 174°, d_4^{20} 1.063, n 1.55746, 1.56277, 1.57641, 1.58865 for α , D, β and γ at 21.65°, n_D^{20} 1.5635, E_Z 0.48, 0.52, 25%, 28% for α , D, β — α and γ — α ; semicarbazone, needles from alc., m. 157–61°; with H and colloidal Pd it gives 1-benzylcyclohexan-2-one, oil, whose semicarbazone, needles from MeOH, m. 166–7°. If the hydrocarbon had had the structure (b) instead of (a) the final product in the above reactions would have been benzoylcyclohexane, whose semicarbazone m. 168–9°, but when the latter is mixed with the above semicarbazone the mixt. m. 120°. 1,3-Dimethyl-5-phenylcyclohexan-5-ol, from PhMgBr and 1,3-dimethyl-3-cyclohexen-5-one, m. 110–1° (Lembert, *Diss. Heidelberg*, 1905, gives 104°), deliquesces more or less rapidly in the air or in a desiccator, but is stable for months in sealed tubes; dehydrated by heating with $KHSO_4$ for different lengths of time or by repeated distn. *in vacuo* or, finally, by directly decomp. the Mg compd. with ice-cold 40% H_2SO_4 , the carbinol always gives crude products boiling within quite wide limits, but all give fractions of the 3,5-diene (c) with about the same const., e. g., b_{117} 148°, d_4^{20} 0.970, n 1.56824, 1.57486, 1.59322, 1.61083 for α , D, β and γ at 17.0°, n_D^{20} 1.5735, E_Z 1.24, 1.33, 59%, 67% for α , D, β — α and γ — α ; with Na and boiling alc. it gives the 3-hexene, b_{114} 131°, $d_4^{18.6}$ 0.9460, n 1.53131, 1.53617, 1.54733 1.55799 for α , D, β and γ , E_Z 0.38, 0.42, 20%, 20%. 1,3-Dimethyl-5-methene-3-cyclohexene (C. A. 5, 505) was again prepd. and its properties were found to agree well with those of the earlier preps.; comparison of its E_Z values (0.99, 1.05, 38%, 41% for α , D, β — α and γ — α) with those of 1,1-dimethyl-4-methenecyclohexa-2,5-diene (1.86, 1.95, 54%, 58%; C. A. 5, 3242) shows that the entrance of a new double bond in the ring produces a considerable increase in the exaltation; it is therefore quite probable that (c) and its analogs prepd. by Klages and co-workers (*Ber.* 40, 2365(1907)), as well as the products obtained by their reduction with Na and alc., have the structures assigned to them by him and accepted by A. and T.

CHAS. A. ROUILLER.

1,3-Dimethylcyclohexan-2-one and 1,2,3-trimethyl-1-cyclohexene. K. v. AUWERS AND F. KROLFFHEIFFER. Marburg. *Ber.* 48, 1226–33(1915).—Attempts to prep. pure 1,3-dimethylcyclohexan-2-one (a) by Haller's method (C. A. 7, 3490) showed that there is formed at the same time the asym. 1,1-Me₂ deriv. in far greater amt. than indicated by H. (1/3 or at least 1/4 of the original ketone), and, moreover, his method of removing the latter by condensation with BzH and NaOEt is impracticable, for the 1,3-Me₂ compd. also condenses. It was finally obtained pure by Kötze and Schaeffer's method (C. A. 6, 2757). 1-Methyl-3-hydroxymethylenecyclohexan-2-one is obtained in 53% yield from 10.4 g. Na wire in 16 cc. Et₂O and 50 g. methylcyclohexanone in 250 cc. Et₂O treated in the cold in the course of 30–45 min. with 60 g. of HCO₂Am (previously shaken 2 hrs. with ignited potash), allowed to stand overnight, decompd. with 335 cc. ice H₂O and acidified with 30% AcOH; it b_{118} 79.2–9.4°, d_4^{20} 1.051, n 1.50149, 1.50664, 1.52123 for α , D and β at 15.4°, n_D^{20} 1.5046, E_Z 0.94, 1.04, 94% for α , D and β — α . Reduced by the K. and S. method it gives (a) which, after purification with ice-cold 2% KMnO₄ (yield, 8 g. from 30 g. HOCH< compd.), b_{118} 53.6–5.3°, d_4^{20} 0.914, n 1.44976, 1.45189, 1.45811, 1.46252 for α , D, β and γ at 11.85°, n_D^{20} 1.4482, E_Z 0.01, 0.01, 2%, —3% for α , D, β — α and γ — α ; semicarbazone, m. 196–7°. 1,2,3-Trimethylcyclohexene, obtained by treating dimethylcyclohexanone, MeI and Mg in the usual way and slowly heating the resulting liquid carbinol with 1.5 parts (CO₂H)₂ to 140–50°, b_{118} 149.6–50.0°, d_4^{20} 0.828, n 1.46015, 1.4646296, 1.47021, 1.47603 for α , D, β and γ at 11.75°, n_D^{20} 1.4593, E_Z —0.11, —0.10, 5%, 3% for α , D, β — α and γ — α ; microchloride, blue oil.

CHAS. A. ROUILLER.

Flavone as the farina of the *Primula* (MÜLLER) 11D. Complex compounds of platinum with tellurium ethers (FRITZMAN) 6.

II. BIOLOGICAL CHEMISTRY.

A. GENERAL.

FRANK P. UNDERHILL.

Chemical nature of enzymes. TH. BOKORNY. *Allgem. Brau.-Hopfen Ztg.* 55, 899-900(1915).—The enzymes investigated were brought in contact with definite quantities of normal H_2SO_4 and NH_3 for prolonged periods, and the free acid and base detd. The expts. showed that trypsin, rennin and emulsin have an acid as well as a base-binding capacity. Diastase (also taka-diastase) showed indifference to acid and pepsin to both acid and alkali. B. sees in the amphoteric character shown by many of the enzymes a strong argument in favor of their protein nature (cf. C. A. 9, 1788-9).

L. W. HAAS.

The lipoids of ancient Egyptian brains and the nature of cholesteryl esters. A. LAPWORTH AND F. A. ROYLE. Univ. Manchester. *J. Path. Bact.* 19, 474-7(1915).—The existence of only one series of esters of fatty acids has been established. The chlorides of the higher fatty acids when heated with cholesterol at moderate temps. yield esters. Above 350° , however, they give aliphatic ketones. The cholesterol of ancient Egyptian brains is present mainly in the form of esters. No appreciable amt. of the higher fatty ketones is to be found in them.

JOHN T. MYERS.

Participation of the intermediate products of alcoholic fermentation in oxygen respiration. LEONID IVANOV. Petrograd. *Ber. botan. Ges.* 32, 191-6(1914).—I. attempts to clarify his position in his controversy with Kostychev. The exceptions taken by I. to the conclusion of K. that normal respiration is stimulated by the intermediate products of alc. fermentation are based upon the following alleged defects in K.'s expts. and reasoning: (1) the wheat germs employed were not capable of germination and were unsuited for the investigation; (2) the pronounced stimulation in the CO_2 excretion of wheat germs, which was observed in sugar solns. fermented by zymin, was not a case of normal respiration, but really represented a stimulation of alc. fermentation, since absorption of O was not correspondingly increased, the amt. of alc., on the contrary, increased and the stimulation even occurred without access of O; (3) boiled zymin ext. alone (without fermented sugar) produced a similar stimulation and the active substances are probably organic and inorganic phosphates (with possibly the coenzyme). K. has in turn repeated some of his expts. and finds that living germs (unlike dead germs and those incapable of germination) do not react to phosphates, and that the respiration of these germs is stimulated by fermented sugar solns. without any change in the relation CO_2/O . I. replies that this stimulation of respiration is then of a quite different character from that first observed by K. since the ratio CO_2/O increased progressively in the 1st expts. in the media H_2O , sugar and fermented sugar, resp. I. concludes that, whatever the nature of the stimulation may be, it has not been proved that it is due to the intermediate products of alc. fermentation. H. S. P.

Away from sugar to betaine (PRINGSHEIM) 10.

B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

Another sensitive iodine test for the practising physician. J. SCHUMACHER. *Deut. med. Wochschr.* 41, 532(1915).—To the urine to be tested H_2O_2 and 1% alcoholic benzidine soln. are added. The upper part of the fluid is heated and becomes intensely brown or black in the presence of I.

S. AMBERG.

The estimation of acetone. N. O. ENGFELDT. Stockholm. *Berl. klin. Wochschr.* 52, 458-9(1915).—A modification of Frommer's test; it will detect 0.001 mg.

of acetone in 10 cc. of H_2O . To 10 cc. of urine distillate add 5 drops of conc. salicylaldehyde and 5 g. of solid KOH and heat the mixt. to 50° on a H_2O bath, then gradually to the b. p. In the presence of acetone the KOH is colored orange or red before it goes into soln., and after going into soln. the whole mixt. has this color. This test is not specific for acetone alone but is for the acetone compds.

JULIAN H. LEWIS.

A simple clinical method for the determination of ammonia in urine. A. A. BONNEMA. Apeldoorn. *Chem. Zig.* 39, 519(1915).—In the first method described (not new) distn. from CaO and C_2H_5OH at atm. pressure is used. Henriques and Sørensen's method (*C. A.* 4, 1622; 5, 1457) is also modified as follows: To 10 cc. urine add 30 cc. H_2O and 5 drops of a 1% alc. soln. of phenolphthalein and titrate with 0.1 *N* NaOH. Then add 10 cc. of CH_2O , previously neutralized with phenolphthalein indicator, and titrate again to the red color, using a 2nd flask containing 10 cc. urine and 30 cc. H_2O for comparison. The NaOH soln. used in the last titration corresponds to the NH_3 combined with amino acids. Purification of the urine with $BaCl_2$ and $Ba(OH)_2$ is unnecessary.

J. H. MOORE.

The Wassermann reaction according to Wassermann himself. E. PALIER. *Med. Record* 88, 62-5(1915).—A description of materials and technic. P. says that the Wassermann reaction is not well understood even in Germany.

A. H. RAHE.

An improved and simplified technic for auto-serotherapy. E. E. PALMER AND WM. LEE SECOR. *Med. Record* 88, 108-9(1915).—An area on the chest of 2 sq. in. is painted with 3% I soln. and after drying a piece of fly blister paper, $1\frac{1}{2}$ in. square, smeared with petrolatum, is applied and protected with a shield. After 12 hrs. one corner of the blister is raised and the serum drawn off and injected at once. The authors believe that serum obtained as above is more active than that from centrifuged blood.

A. H. RAHE.

C. BACTERIOLOGY.

ERNEST D. CLARK.

Classification of Streptococci by fermentation. J. G. HOPKINS AND A. LANG. *J. Infect. Dis.* 15, 63-84(1914).—*Streptococci* in infections of man may be differentiated from the common saprophytes by fermentation of a broth colored with litmus containing 2% or more of peptone and 1% of the carbohydrate, with an initial reaction of 0.0 and 0.5% normal acidity to phenolph. With these reactions one pathogenic and six saprophytic forms are recognized. The amt. of acid produced is of no value in classification. The hemolization of human blood is of value, while the coagulation of milk and the neutral red reaction are not reliable.

J. GAUB.

Indole reactions in the case of proteus bacilli. E. A. R. F. BAUDET. *Folia Microbiol.* 2, No. 3; *Chem. Zentr.* 1914, I, 1845.—Indole reactions were tested in the case of peptone-NaCl solns., the distillate from the cultures, the nutrient soln. of Zipfel and the nutrient substrate of Berthelot. The following points must be observed in order to obtain satisfactory results in qual. tests for indole: (1) the *p*-dimethylamino-benzaldehyde reagent of Ehrlich is recommended because of its sensitiveness; (2) the Zipfel soln. should be employed as a nutrient medium; (3) in default of the Zipfel soln. accurate results can only be obtained by means of distn. of the cultures.

H. S. PAINE.

D. BOTANY.

CARL L. ALSBERG.

The occurrence of flavone as the farina of the Primula. HUGO MÜLLER. Davy-Paraday Lab. Roy. Inst. *J. Chem. Soc.* 107, 872-8(1915).—The mealy secretion or "farina" on the leaves, stalks and seed capsules of many species of *Primula* was shown to consist almost entirely of flavone, $C_6H_4.O.CPh:CH.CO$ (A), silky tufts, m. $99-100^\circ$,

identical with the compd. synthesized by Kostanecki and Feuerstein (*Ber.* 33, 333), which when decompd. by cold $\text{Ba}(\text{OH})_2$ in MeOH yielded *o*-hydroxydibenzoylmethane (B), $\text{HO} \cdot \text{C}_6\text{H}_4\text{COCH}_2\text{Bz}$, pale yellow prisms, m. 120° (goniometric data given in detail), which when heated in aq. NaOH formed AcPH, *o*- $\text{HO} \cdot \text{C}_6\text{H}_4\text{CO}_2\text{H}$ and some BzOH. Acetate of (A), needles, m. 118° . Although many of the yellow plant coloring matters are derivs. of (A), its physiological function in the life of the species *Primula* remains unknown. The excretion of (A) does not appear to be a necessary result of the life process, since in a number of plants raised from the seeds of *P. denticula* and *P. capitata*, there were some perfectly healthy leaves which did not secrete (A).

LOUIS E. WISE.

A biochemical study of nitrogen in certain legumes. ALBERT L. WHITING. Illinois Agr. Expt. Sta., *Bull.* 179, 471-542(1915).—This bulletin deals with the biochemical nature of N especially with reference to its fixation and assimilation through the symbiotic relationship of *Bacillus radicicola* and certain members of the Leguminosae. After a consideration of the historical features of the problem, W. takes up biological and chemical considerations as reported in the literature, and in addition, discusses the theories of assimilation, fixation and immunity in connection with published data. The exptl. part of the bulletin is divided into 2 parts. Part I consists of studies made to det. the organs through which legumes obtain their N from the air. The expts. reported show conclusively that the cow pea and the soy bean utilize atm. N through their roots and not through their leaves. No combined N could have been assimilated in the expts. as carried out. Part II is concerned with an attempt to det. more definitely the mechanism of the reactions occurring in the fixation and assimilation of atm. N by *B. radicicola* and legumes. The legumes employed were the soy bean and the cow pea. About 74% of the N of cow peas and soy beans at the time of harvest is in the tops, the roots and nodules containing the remainder. This reverses the results found in the earlier periods of growth. About 45% of the sol. N, as an average, was found in the tops, 34 in the roots; in the nodules of the soy beans, 14%, in cow pea nodules, 34%. The N pptd. by phosphotungstic acid averaged in the tops of both soy beans and cow peas about 12% of the total N; in the roots 5.5%, in the nodules of soy beans 1%, in the nodules of cow peas 17%. "Other forms of sol. N than those pptd. by phosphotungstic acid and NaOH occur. In these series they constituted as an average in the tops of both soy beans and cow peas about 68% of the sol. N, in the roots 77%, in the nodules of soy beans 89%, and in the nodules of cow peas 53%." Fixation takes place early and is rapid in some cases, especially with cow peas. "Plants grown under the conditions of these experiments contain no NH_3 , nitrites nor nitrates." B. E. B.

F. PHYSIOLOGY.

ANDREW HUNTER.

The pigment granules of the hepatic cells. I. ANDRÉ MAYER, FR. RATHERY AND GEORGES SCHAEFFER. *J. physiol. path. gen.* 16, 581-96 (1914).—These granules are very sol. in EtOH, MeOH, but less so in the higher alcohols; they are also sol. in Et_2O , EtOAc, CHCl_3 , CCl_4 , pyridine; slightly sol. in CS_2 and C_6H_6 ; insol. in petroleum ether, the aldehydes and ketones. The solubility is altered by salts of the heavy metals. The extent of oxidation varies with the agent used, concn. and time of exposure. The effects of gram stain, Hübl soln., Br water and of Cr-OS mixt. are given. II. *Ibid* 16, 607-22(1914).—Two types of reactions follow injection of various substances (organic acids and bases, anesthetics). Type 1 is cytolytic and chromolytic, and is characterized by the progressive disappearance of the chromatic granules and the increasing lability of the protoplasm. Type 2 is one of protoplasmic homogenization. There is an increase in the vol. of the granules and a fusion with the cellular protoplasm.

A. H. RAHE.

The influence of the spleen on the localization of iron in the organs of the pigeon, particularly the liver. PAUL CHEVALLIER. *J. physiol. path. gen.* 16, 638(1914).—The injection of human hemoglobin into the pigeon causes an excess of Fe in the cells of the spleen and other organs, particularly the lymph nodules and intercapillary cells of the liver. After splenectomy there is added to a polyblastic siderosis a considerable siderosis of the parenchyma. The former indicates a process of assimilation of Fe, the latter one of excretion. The spleen tends to prevent the elimination of Fe and appears to be an organ of assimilation of Fe.

A. H. RAHE.

G. PATHOLOGY.

H. GIDEON WELLS.

Observations and researches on the pyrogenic and antigenic action of the proteins of the typhoid bacillus on man, especially the aged. VALENTINO SEBASTIANI AND CARLO GALASSI. *Arch. farm. sper.* 19, 367-411(1915).—Intravenous injection of the optimum dose of typhoid serum for the formation of agglutinins and bacteriolysins, does not give rise within a period of 9 days to the antibodies of Bordet-Gengou. The production of agglutinins bears no strict relation to the degree of febrile reaction, and is much lower in the case of old men. In both aged and normal subjects, there is marked leucocytosis, which consists in an absolute and relative increase of the polynucleated neutrophiles.

A. W. DOX.

Tuberculosis antibodies and tubercular hypersensitiveness. E. UNGERMANN. *Arb. kais. Gesundh.* 48, 381-411(1915).—I. Even in the case of animals rendered actively immune there is no reason to believe that, in the case of tuberculosis immunity, phagocytic serum bodies play an important part. Sera, capable of developing distinct phagocytic activities even in such diln. as 1:100, were not obtained as a result of immunization, while the opsonic index frequently attained considerable values. A specificity of the phagocytes of the animals rendered immune by means of the serum, which might render possible a differentiation of the *Typhus humanus* and *bovinus* could not be established. An appreciable intensification of the tubercle bacilli phagocytosis in the peritoneum of guinea pigs which had been treated with highly active tuberculosis immunoserum was not observed. A soln. of the tubercle bacilli in the peritoneum of tubercular guinea pigs was repeatedly seen, but such was also frequently the case in normal animals. II. Classified according to their toxic action upon tuberculous animals the preparations examined rank as follows: (1) Live bacilli with a lethal dose of from 0.3 to 0.5 mg. (2) Bacilli killed in accordance with Loeffler's process, from 0.1 to 1 mg. (3) Bacilli ground and killed in steam, 1 mg. (4) Tuberculin, 0.03 cc. (5) Filtered bouillon culture, 0.3 cc. By the use of dead tubercle bacilli it is possible to produce a hypersensitiveness in guinea pigs and rabbits, the detection of which, however, is more difficult and requires larger antigen doses than is the case with infected animals. The most favorable, because comparatively regular, action was obtained by means of the bacilli killed in accordance with Loeffler's method. Old tuberculin employed repeatedly in large doses did not bring about any sensitiveness in guinea pigs. This is correlated with the absence of any irritation on the part of the tuberculin in spite of the antigen content present. In three instances with guinea pigs and one with rabbits, the reaction for hypersensitiveness took the acute form of anaphylactic shock, twice after injection of bacilli and twice after injection of tuberculin. In 7 cases death due to hypersensitiveness occurred within the 2nd to 4th days. Many of the animals which survived the longer period showed pneumonic changes in the lungs without the discovery of any specific bacteria. These acute processes of inflammation are believed to be the symptoms of tuberculous allergy. In many guinea pigs treated intravenously with large doses of dead bacilli, local conditions were discovered which showed great similarity with those of active tuberculosis; foremost among these was a marked en-

largement of the spleen. Hypersensitiveness could not always be produced in these animals.

C. A. NOWAK.

Some comments on a new antiserum for cancer. WILLIAM N. BERKELY. *N. Y. Med. J.* 102, 45-7(1915).—Local remedies for cancer (X-rays, Ra, fulgulation) rarely meet indications in full because typical cancers metastasize and secondary growths develop in vital organs. The antigen is obtained by extn. of fresh, unpreserved tumor with water and pptn. of nucleoproteins and globulins. 3 weeks after injection into sheep, antibody is demonstrable by the complement-fixation test. Serum should be used after primary operations. Owing to its protein nature the antiserum excites formation of anti-antibodies and its effect upon extensive growths is palliative only.

A. H. RAHE.

Studies on the toxicity and hemotoxicity of normal and anti-sera. I. M. NICOLLE AND E. CÉSARI. *J. physiol. path. gen.* 16, 680-9(1914). II. *Ibid* 696-703.

A. H. RAHE.

Further experiments on the poisons of the spiders (*Epeira diadema* Walck). L. E. WALBUM. *Statens Seruminst., Copenhagen. Z. Immunitt.* 23, 623-84(1915).—The chief poison found in exts. of these spiders, and called epeiratoxin, seems to be formed in the ovaries, passing only in small amts. into the blood; it is found only in females, and most during active egg production. The poison of the salivary secretion seems to be quite different; it is much weaker but strong enough to kill flies. Epeiratoxin is antigenic, and the antitoxic serum can prevent death from lethal doses of the poison. The hemolysin, epeirialysin, is identical with arachnolysin, and seems to be formed in the same place as the toxin, and to form antitoxin under the same conditions. In exts. of spiders the lysin is found chiefly in the albumin fraction, while the strong tryptic enzyme of the saliva is pptd. with the globulin. This enzyme does not cause an increase in the antitryptic power of the blood of animals immunized with it.

H. G. W.

Do the exhalations of mice possess anaphylactogenic properties for the serum of the same animals? TH. MESSERSCHMIDT. *Univ. Strassburg. Z. Immunitt.* 23, 685-90(1915).—No anaphylactic sensitization could be obtained with the salt soln. through which had been passed the air from a jar containing mice for long periods, thus failing to substantiate the work of Rosenau and Amoss (cf. C. A. 5, 3590).

H. PHARMACOLOGY.

ALFRED N. RICHARDS.

Treatment of internal leishmaniosis. G. DI CRISTINA AND G. CARONIA. *Deut. med. Wochschr.* 41, 396-7(1915).—Children with leishmaniosis were treated with intravenous injections of Sb tartrate in 1% aq. soln. beginning with 0.02 g. and increasing the dose to 0.1 g. Five cases recovered, 2 are on the road to recovery, and 1 died after a transitory improvement with acute nephritis. The action of the remedy is not sufficiently known, but after the first injections a deformity of the cytoplasm of the parasites is seen.

S. AMBERG.

A new salvarsan preparation, "salvarsan-sodium." T. FABRY AND A. FISCHER. *Münch. med. Wochschr.* 62, 612-4(1915).—"Salvarsan-sodium" contains about 20% As and is easily sol. in water. It was given intravenously in average doses of 0.45 g. in 50 cc. 0.4% NaCl with good results.

S. AMBERG.

Study of the curarizing action of scopolamine. ALBERT OBRÉ. *J. physiol. path. gen.* 16, 655(1914).—Scopolamine suppresses indirect nerve excitation. It does not prevent nerve response by its local action.

A. H. RAHE.

Michael Servetus' book on syrups. CHARLES GREENE CREMSTON. *New York Med. J.* 102, 165(1915).—Historic note on Servetus' therapeutic dissertation written in 1537. A. H. RAHE.

Contra-indications to the intra-abdominal use of oil. WATERS F. BURROWS. *Med. Record* 88, 66-7(1915).—B. detd. by animal expts. that pure mineral oil poured into the peritoneum caused no ill effect. After opening the cavity, oil was found to be partially emulsified. There were no adhesions. Microscopic exam. showed no signs of peritoneal exudate and leucocytes were absent. With impure oil or in the presence of infection the oil thickened, caused adhesions and large numbers of leucocytes were present. Sweet, Chaney and Wilson (*Ann. Surg. Mar.*, 1913) have shown that these leucocytes have decreased phagocytic action. A. H. RAHE.

12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

Revision of the Edible Fats and Oils Section of the Swiss Food Regulations. KREIS, *et al.* *Mitt. Lebensm. Hyg.* 5, 367-82(1914).—Methods for the analysis of edible fats and oils including butter, margarines and cooking compounds are given in detail. Definitions and standards for table butter, cooking butter, melted butter, margarine, beef tallow, lard, coconut oil, cooking compound, olive, nut (walnut), poppy, sesame, peanut, cottonseed and kapok oils together with the particular detns. to be made on each of these products are included in the regulations. H. S. BAILEY.

The avocado in California. I. Culture, production and marketing. IRA J. CONDIT. II. Composition and food value. M. E. JAFFA. College of Agr. Expt. Sta., *Bull.* 254, 381-402(1915).—Analyses of 28 varieties are given. The avocado is easily digestible and is an excellent source of vegetable fat. E. H.

Aldehyde color reactions. Contribution to the detection of artificial invert sugar, especially of caramel. D. SCHENK AND H. BURMEISTER. Saarbrücken. *Chem. Zig.* 39, 465-6(1915).—Investigations like those of Schenk (cf. C. A. 8, 2006) were made with phenol, β -naphthol, pyrocatechol, resorcinol, hydroquinol, guaiacol, pyrogallol, phloroglucinol, salicylic acid, salol, thymol and vanillin, and the color reactions tabulated. The phenol-H₂SO₄ and guaiacol-H₂SO₄ reactions are best, the latter being more delicate. The tests are to be carried out as in the previous work.

J. H. MOORE.

Composition of corn (maize) meal manufactured by different processes and the influence of composition on the keeping qualities. A. L. WINTON, W. C. BURNETT AND J. H. BORNHANN. Bur. of Chemistry, U. S. Dept. of Agr., *Bull.* 215, 31 pp. (1915).—The authors' main purpose is to show the general compn. of American table meal milled by different processes and especially the keeping qualities of the extreme types dried to different degrees and stored in different localities. The products of a white-corn mill may be arranged in the following order in regard to acidity, fat, fiber and ash, beginning with the lowest percentage: grits, meal, flour, feed, germ; in the following order in regard to protein: flour, meal, grits, feed, germ. The N-free ext. is not strikingly different in grits and meal but is lower in the feed and lowest in the germ. Samples of meal taken from 41 mills located in 32 towns and 17 states are classified as (1) whole-kernel, stone-ground meal; (2) bolted, unde germinated meal; (3) degerminated, bolted, roller-ground meal ("cream meal"); and (4) low grade or "standard" meal. Class 1 at time of grinding has the same compn. as corn except in moisture but soon develops a greater acidity. Class 2 contains less fiber than the corn but no other general rule can be formulated, owing to the variable manufacturing

conditions. Class 3 contains less protein, fat, fiber and ash and more N-free ext. than the corn. Class 4 contains sometimes more and sometimes less of each constituent than the corn. Ton and carload lots of degerminated bolted meal with a range in moisture content were stored at Savannah and Chicago. A study of the analyses of these samples made at intervals up to 6 months indicates that degerminated, bolted meal containing not over 14% moisture and 1% fat as detd. by the A. O. A. C. method, properly stored, should keep for 6 months; with a moisture content of 15% it should keep for 3 months. Comparative tests with whole-kernel and degerminated, bolted meal, undried and dried to different degrees and stored at Savannah and New Orleans showed the superior qualities of the latter. Whole kernel meal should be produced locally and consumed soon after grinding; properly dried, degerminated meal keeps well during transportation and long storage.

P. B. DUNBAR.

Changes in bread on aging. M. P. NEUMANN. *Z. ges. Getreidew.* 6, 119-22 (1914).—The fact that the crumb of fresh bread has a greater capacity for absorbing H_2O than has the crumb of old bread indicates that the changes which occur during the aging of bread are not due exclusively to loss of H_2O . This view is also confirmed by expts. which showed that a fresh 2 kg. loaf of rye bread lost 1.18, 1.01 and 0.96% in wt., resp., during each of the 1st 3 days and 1.14-3.15% during each 3-day period thereafter until a total age of 27 days had been reached, while staleness ensues after a period varying from several hrs. to 1-2 days with a corresponding loss in H_2O of 1-2%. It is extremely probable that the aging of bread is primarily due to the influence of loss of H_2O on the colloidal system starch- H_2O ; in view of the high concn. of the starch (as starch paste) a very slight change in the H_2O content would be expected to exert considerable influence on the system. The H_2O liberated by the sepn. of amorphous starch is partly evapd. and partly absorbed by the albumin coagulum; a progressive sepn. of amorphous starch is thereby produced and the staleness of bread is essentially due to this coagulation of starch from the paste to the amorphous form. The efficacy of preps. which are employed for retarding the progress of aging is due exclusively to their property of rendering the liquefaction of starch more complete. The above view is consistent with the results of Katz who ascertained the existence of a physico-chem. equil. in the crumb; the fresh condition is the stable form at higher temps. (50-100°), while the stale condition is the stable form at lower temps. (25-0°). It is suggested that further valuable data may be obtained by correlating the rate at which bread becomes stale with the physical and chem. nature of the starch grains, as well as with the mineral (phosphates, Ca salts, etc.) constituents of the flour and the NaCl which is added to the dough.

H. S. PAINE.

New constant for the investigation of partial separation of fat from milk. RENE LEDENT. *Bull. soc. chim. belg.* 28, 229-34 (1914); *Ann. chim. anal.* 20, 77-81 (1915).—Vandam has proposed (cf. *C. A.* 8, 3602) to employ the relation c/g (c and g = contents of casein and fat, resp.) as a criterion of the partial sepn. of fat from milk; the value of c/g is greater than unity in the case of milk from which the fat has been partially sepd. L. proposes to employ a new coeff. C/V obtained by dividing the Cornalba factor C by the Vandam index V . The cream was sepd. from milk containing 3.0% fat ($C/V = 7.54$) so that the fat content was reduced to 0.3%. This cream was then added in varying amt. to the residual milk so that samples were prepd. which contained 0.3, 0.5, 0.6, 0.7, 1.4, 1.7, 1.9, 2.7% fat; the corresponding values of C/V were 0.80, 1.40, 1.61, 2.11, 3.80, 4.32, 5.22, 6.06. Exam. of 40 samples of milk (each from a single cow) showed a variation of 6.12-20.50 in the value of C/V ; the smallest value of fat content was 2.30% and the corresponding value of C/V was 6.34. A pure milk showed values for fat content, Cornalba coeff., Vandam index and C/V of 2.7, 6.71, 0.98, 6.84 and 2.35, 7.00, 1.20, 5.83, resp., before and after sepn. of fat;

another sample of pure milk showed corresponding values of 3.4, 6.62, 0.75, 8.82, and 1.8, 6.82, 1.53, 4.45 before and after sepn. of fat. The preceding data indicate that a sample of milk which shows a value of C/V less than 6.0 may be considered to have undergone partial sepn. of fat. It is possible, however, for milk containing an unusually high % of fat to show a value of C/V greater than 6.0 after slight sepn. of fat. The relation C/V , as well as the Vandam index, may be considered to be a reliable criterion for partial sepn. of fat in the case of the ordinary grades of milk which contain a medium % of fat.

H. S. PAINE.

The alcohol test in relation to milk. S. H. AYERS AND WILLIAM T. JOHNSON. U. S. Dept. Agr., *Bull.* 202, 35 pp. (1915).—Exptl. work to det. the practical value of the alc. test for the quality of market milk is given. The alc. test may be positive as a result of the growth in milk of lactic acid and rennet-forming bacteria; there is no definite relation between the alc. test and the number of bacteria in milk. If samples from a single cow or small herd show a positive 68% alcohol test some change in the milk from its normal condition is indicated and a more careful exam. of the herd should follow. With mixed market milk other factors present themselves for consideration. In these cases the alizarol test may be of more value than the plain alc. test to give additional information as to the kind of fermentation. Acid and rennet fermentation may be differentiated by neutralizing the acidity by sodium hydroxide. Considerable literature is cited.

E. H. INGERSOLL.

Milk powder. G. CORNALBA. *Boll. chim. farm.* 54, 34-7 (1915).—C. traces the origin and progress of the attempts to secure milk in more stable form (both as condensed or evapd. milk and milk powder) by evapn. of H_2O ; he discusses the methods of Appert and Martino De-Lignac (who were the first to make progress in this direction) as well as the later procedures of Legripp, Ellin, Just-Hatmaker and the recent, more nearly perfect method employed for the prep. of "Verolatte" ("Trufood"). The last method is considered to approach very nearly to a soln. of the problem of obtaining H_2O -free milk with retention of the desirable organoleptic and nutritive properties of fresh milk. The contents of H_2O , fat, casein, lactose and ash in a sample of the Hatmaker milk powder were 8.00, 28.70, 22.70, 35.10 and 6.50%, resp.; the contents of H_2O , fat, nitrogenous substance, sugar and ash in the "Verolatte" milk powder were 1.54, 30.70, 26.43, 35.32 and 6.01%, resp.

H. S. PAINE.

The milk question. III. L. HORON. Liège. *J. pharm. Anvers* 1914, 401-7; *Bull. soc. chim. belg.* 28, 246 (1914).—H. discusses the efficacy of pasteurization and the use of the alc. reaction for investigating the quality of the milk of commerce.

H. S. PAINE.

Pasteurizing milk in bottles and bottling hot milk pasteurized in bulk. S. HENRY AYERS AND W. T. JOHNSON. U. S. Dept. Agr., *Bull.* 240, 27 pp. (1915).—Pasteurization in bottles using a temp. of $145^{\circ}F$. for 30 min. causes satisfactory bacterial reduction. The bottles must have perfect water-tight fitting caps; their capacity must be sufficient to allow for expansion and contraction of the milk in the process. Great care is necessary to insure that all the milk has been heated to $145^{\circ}F$. for 30 min. Another process is to bottle the milk hot, cap with cardboard caps and cool by an air blast. Commercially these processes although more time consuming have the following advantages: bottle infection can be eliminated; milk losses from evaporation are eliminated and ordinary cardboard caps can be used.

Ger., 283,468, Mar. 20, 1914. R. WOELFERT. In the production of distilled water, the H_2O is volatilized under partial vacuum produced by a steam injector which serves to carry the vapors through a diffuser, into a superheater and on into the condenser. The condensate is used as boiler feed water. The coils used for heating the supply of H_2O may be used as cooling elements.

15. SOILS AND FERTILIZERS.

R. O. E. DAVIS.

Determination of sulfate in soils. P. E. BROWN AND E. H. KELLOGG. *J. Ind. Eng. Chem.* 7, 686-7(1915).—Sulfates cannot be extd. from soils by treatment with dil. HCl because of the interference of organic substances and Fe compds. while with strong acids SiO_2 is also dissolved. All the sulfates present can be extd. by 6-8 hrs.' shaking with twice the wt. of H_2O . In a supplemental investigation it was found that the S photometer yields accurate and rapid results. ISADOR MILLER.

Chemical studies of soils. S. TIJMSTRA. *Meded. Deli Proefstat. Medan* 8, No. 8, 244-65(1914); *Expt. Sta. Record* 33, 22.—Comparative chem. and physical studies of 8 plats subjected to different cultural treatments gave results showing decided variations. The differences, in certain instances, were attributable to the plowing under of the ashes of burnt weeds. This treatment was accompanied by a decrease in the content and solubility of P_2O_5 , a decrease in Mg and Fe and an apparent increase in K and Cl. B. E. B.

Some preliminary investigations into the chemical composition of certain vineyard soils in the Montagu and Robertson districts. ABRAHAM IZAK PEROLD AND DAVID CHAMBERS CRAWFORD. *S. African J. Sci.* 11, 337-49(1915).—HCl exts. of numerous soils were analyzed and the results are discussed. W. H. FRY.

Availability of organic nitrogen. J. E. BRECKENRIDGE. *J. Ind. Eng. Chem.* 7, 671-3(1915).—Chairman's address before the Fertilizer Division of the Am. Chem. Soc. The paper contains no new, original data but reviews recent work on the subject. ISADOR MILLER.

Experiments to determine the influence of the fineness of subdivision and richness in magnesium carbonate of crushed limestone used for amendment of acid soils. WALTER THOMAS AND WILLIAM FREAR. Penna. State College, Agr. Expt. Sta., *Ann. Rpt.* 1912-13, 206-19.—The following subjects were studied: (1) To what degree of fineness should limestone be crushed to secure the best economic return from its use? (2) What influence upon plant development has the MgCO_3 contained in varying proportions in the different limestones? Limestone of 20-, 40-, 60-, 80- and 100-mesh was tried; the yield of red clover following the use of 40-mesh limestone was about $5\frac{1}{2}$ times that with the 20-mesh. The 60-mesh gave a yield $\frac{1}{2}$ greater than the 40-mesh, the 80-mesh $\frac{1}{4}$ greater than the 60-mesh. The extra costs involved in grinding finer than 60-mesh makes the 80- and 100-mesh unprofitable and doubtless unnecessary. Paraffined pots, $5\frac{1}{2}$ in. diam. $\times$ 7 in. depth, were used. Two soils, of varying degree of acidity, were used in the test. The authors recommended, as a result of their tests, that limestone at least 60-mesh in fineness should be used when the use of limestone is indicated. Dolomite gave practically the same yield as pure limestone. B. E. B.

The utilization of the nitrogen and organic matter in septic and Imhoff tank sludges. C. B. LIPMAN AND P. S. BURGESS. Calif. Agr. Expt. Sta., *Bull.* 251, 287-95(1915).—The N content of the sludges examd. varied from 1.23 to 2.66% and P_2O_5 from 0.77 to 1.82%. Availability studies, in which sludge was mixed with different types of soil, showed that there are variations in the same soil, and that the different soils vary markedly in this respect. As a rule, however, the amt. of nitrates formed from sludge was greater than in the case of materials like dried blood, tankage, etc. B. E. B.

Preparation of fertilizer from municipal waste. J. W. TURRENTINE. *Am. Fertilizer* 43, 37-44(1915).—The classes of city waste are given as: ashes, rubbish, sewage, street sweepings, trade waste, dead animals and garbage. The compn. and

availability of the various materials are discussed. Sewage and garbage presents the greatest difficulties of disposal. Garbage is best disposed of either by incinerating or by rendering; both methods are described. B. E. B.

Utilization of prickly pear as a fertilizer. J. H. JOHNSTON AND H. TRYON. *Rpt. Prickly Pear Travel. Com., Queensland 1912-14*, 25-6; *E. S. R.* 33, 25(1915).—A brief description of the use of the prickly pear as a fertilizer as practised in Madras, Mysore and the Bombay Presidency of India. B. E. B.

New experiments with carbon dioxide as fertilizer. H. FISCHER. *Ern. Pflanz.* 11, 11-2(1915); *Z. angew. Chem.* 28, II, 215.—Plants fertilized with CO_2 (by introducing this gas into the glass-house) gave more than double the yield of unfertilized plants, thus corroborating previous results. Similar results were obtained by Löbner but he reported an objectionable after-effect. The question of the after-effect will be further investigated by F. R. O. E. D.

Calcium cyanamide and its application. B. SCHULZE. Breslau. *Deut. Landw. Presse* 41, 761(1914); *Z. angew. Chem.* 28, II, 110.—Granular cyanamide is only about $\frac{1}{2}$, as efficient as that finely ground. Tar-oil, added to prevent dusting, does not appreciably affect its efficiency. R. O. E. D.

The effect of different methods of inoculation on the yield and protein content of alfalfa and sweet clover. A. C. ARNY AND R. W. THATCHER. *J. Am. Soc. Agron.* 7, 172-85(1915).—Alfalfa grown in soil inoculated with soil from an old alfalfa field plus CaCO_3 contained more protein than in the case of other methods of inoculation and produced a larger crop of dry material. Commercial cultures applied to seed and to soil increased the dry material produced and the % of protein over the check. Inoculation increased the ash content of the roots and decreased it in the tops of the plants; the % of P_2O_5 in the ash was not effected, while K was higher in uninoculated plants. J. J. SKINNER.

The action of certain new nitrogenous fertilizers on sandy and upland moor soils. B. TACKE. *Mitt. Ver. Förd. Moorkultur deut. Reiche* 32, No. 23, pp. 411-42(1914); cf. *C. A.* 8, 195.—With oats, rye and potatoes grown on sandy and moor soils, the effects of NH_4NO_3 , $\text{Ca}(\text{NO}_3)_2$, urea, and superphosphate prepared with synthetic HNO_3 equaled those of NaNO_3 and $(\text{NH}_4)_2\text{SO}_4$. B. E. B.

Bacteriology of the general fertilizer plats. III. Ammonifications. GUY C. GIVEN. Penna. State College, Agr. Expt. Sta., *Ann. Rpt.* 1912-13, 200-6.—The velocity of NH_3 production was studied in 5 plats of the "General Fertilizer Series" by inoculating sterile portions of a carefully prepared fertile soil mixture containing 65 mg. of N added in the form of cottonseed meal, with like suspensions of the bacteria from the several plats under examn. The amt. of NH_3 was detd. each successive day for 7 days. The amt. produced was practically equiv., irrespective of the field treatment. The same applied when dried blood was used. In the nitrification studies, however, using $(\text{NH}_4)_2\text{SO}_4$, some marked differences were obtained, noticeably where a considerable degree of acidity existed in the soil. B. E. B.

The origin, composition, and fertilizer value of the bat guano of Cuba and the Isle of Pines. C. N. ACKTON. *Modern Cuba* 3, 48-59(1915); *Exp. Sta. Rec.* 33, 24.—The fertilizing value of guano is discussed. Its compn. varies widely. On the basis of analyses of samples from Cuba, Porto Rica and Haiti, bat guano contains as an average 3.5 to 7.0% P_2O_5 , 1.5 to 3.0% K and 8 to 11% N. The fresh friable bat excrement, which usually occurs as a thin cover over the floor of the cave, is easily distinguished from the other material. The light-colored deposit contains large amts. of CaCO_3 and CaSO_4 and more P_2O_5 than fresh guano. The reddish deposits contain more P_2O_5 and very little N. J. J. SKINNER.

Improving Iowa's peat and alkali soils. W. H. STEVENSON AND P. E. BROWN. Iowa Agr. Expt. Sta., *Bull.* 157, 43-79(1915).—A study of shallow Iowa peat soils and alkali conditions in fields. Physical improvement should come first, then the question of fertilizing. The "alkali" spots are best remedied by liberal application of manure or plowing under of straw and green crops. B. E. B.

Phosphates in Massachusetts. Agriculture, importance, selection and use. WM. P. BROOKS. Mass. Agr. Expt. Sta., *Bull.* 162, 131-67(1915).— P_2O_5 is not relatively deficient in Mass. soils. The general results of two series of expts. comparing different phosphates, one extending over 12 and the other over 18 years, are presented. These results indicate that the application of at least a moderate amt. of phosphate is usually profitable, and that the more sol. and available materials give results much superior to those obtained with the finely ground rock phosphates. It is shown that the dissolved phosphates favor more rapid early growth, earlier and more perfect maturity and larger yields than the rock phosphates, and that the former are used with greater profit than the latter. B. E. B.

Chemical control of cattle dipping tanks. CORNELIUS WILLIAMS. *S. African J. Sci.* 11, 287-96(1915).—Sodium arsenite solns. were analyzed after standing various intervals, and the conclusion that oxidation is negligible in solns. made up with distd. water but is very rapid when excretory matter is present is confirmed. Oxidation in tanks is greater in summer than in winter. While a dipping tank is in constant use there is less risk of oxidation than when the tank is idle. Addition of carbolic acid or any of the coal-tar disinfectants arrests oxidation of the dip fluid, if used in sufficient quantity. One or 2 gallons of disinfectant to 1000 gallons water is considered sufficient. W. H. FRY.

Biochemical study of nitrogen in legumes (WHITING) IID. American wild mustard seed (WINTON) 27.

U. S., 1,147,926, July 27. W. B. CHISHOLM. Fertilizer is made by mixing ground phosphate rock with S, steaming to initiate the formation of sulfuric and phosphoric acids and then tightly packing the moistened mixt. to prevent escape of moisture.

Ger., 283,311, July 29, 1913. G. GREYER. In the treatment of diseased plants, the liquid volatile insecticides commonly used are solidified in admixt. with glue, gelatin, or the like, and H_2O , and applied in this form to the affected parts. Glue is dissolved in 10 parts of H_2O , and CS_2 is added, in small amts. at a time, with gentle stirring. Ninety or more parts of CS_2 can be retained mechanically by 1 part of glue. The gelatinous or solid end-product is applied, *e. g.*, to *Phylloxera vastatrix* on the vine. The volatilization of the CS_2 progresses very slowly.

16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

Quantitative determination of the higher alcohols in cognac. L. SETTIMI. *Ann. lab. chim. cent. delle Gabelle* 7, 163(1914); through *Ann. chim. applicata* 3, 373(1915).—To 10 cc. of the alc. to be examd., previously distd. and brought to 50%, add $\frac{1}{2}$ cc. 1% benzaldehyde in very pure 50% alc., then little by little 10 cc. concd. H_2SO_4 , allowing the latter to run down the walls of the vessel, and rapidly mix the whole contents. After $\frac{1}{4}$ hr. the liquid, if it contains higher alcs., presents a more or less intense cherry red color, and should be compared in a colorimeter with the color

given by a liquid made up in the same way from a soln. of 0.5 g. isobutyl alc. in very pure 50% EtOH. The results are slightly higher than those obtained by Rocque's method, which, however, is less simple and rapid than the new method.

S. LEVY.

Phosphoric acid. P. EQUETER. *Mons. Bull. assoc. inst. sup. brass. Gand* 20, 162-6(1914); *Bull. soc. chim. belg.* 28, 246(1914).—E. discusses the use of phosphoric acid in fermentation.

H. S. PAINE.

The adulterations of tannins used in liqueurs. F. REPITON. *Ann. fals.* 8, 118-23(1915).—Tannins extd. from galls with alc. or ether are used in the prepn. of liqueurs such as vermouth. These are sol. in 95% alc. and have a tannic acid content of 82-86% with 12-14% water. One sample of the commercial tannin when treated with 95% alc. left a cryst. deposit of sucrose. For detg. the tannic acid content of these preps. the hide-power method is satisfactory.

H. S. BAILEY.

Adulteration of crude and refined tartrates. P. CARLES. *Ann. chim. anal.* 20, 147-51(1915); *Ann. fals.* 8, 125-8(1915).—The inert Ca tartrate in K H tartrate is valueless for the manufacture of baking powder. In disguising its presence by addition of KHSO_4 to cream of tartar, a double fraud is committed: (1) the acidity is increased and the prepn. consequently sells at too high a price; (2) the physiol. action of the K_2SO_4 and Na_2SO_4 produced in the reaction with NaHCO_3 is different from that of the desired Na K tartrate. *Recognition of this adulteration:* Crude, simply ground material is sepd. by means of a sieve into finer and coarser particles. Both portions are examd. separately. About 10 g. of the fine powder are agitated with 50% alc. for 10 min. in the cold. In presence of KHSO_4 the filtrate presents an excessively high acidity and gives an abundant ppt. with BaCl_2 and even with CaCl_2 , if very much KHSO_4 is present. The coarser particles are dropped from a considerable height on a sheet of blue, damp litmus paper, spread on a shallow dish. After a few min. the KHSO_4 particles become visible, due to the formation of red spots on the litmus paper; they may be picked out and individually characterized. With refined impalpable powders the detection of a fraudulent admixt. of KHSO_4 is much more delicate, but not less important. The mere sulfate (or even bi-sulfate) content is not always indicative of a fraudulent intention, as these substances may be introduced by the process of manuf., when an excessive amt. of KHSO_4 is employed for the conversion of the Ca tartrate in the lees into K H tartrate and the latter only poorly purified. C. proposes that not more than 0.75% sulfate, calcd. as K_2SO_4 , and 0.25% Ca tartrate be tolerated in commercial K H tartrate.

L. W. HAAS.

Practical points concerning fermentation waste with a description of a new process for pressing yeast. WALTER SCOTT. *J. Inst. Brewing* 21, 391-416(1915).—S. deals largely with excize measures, discusses the reasons why the waste figures of any 2 breweries are rarely, if ever, comparable within narrow limits, describes the methods adopted for the sepn. of "barm ale" from skimmed yeast, and gives an account of his efforts to improve the existing method of dealing with waste yeast. The essential feature of S.'s new process is the application of compressed air for pressing skimmed yeast. The latter is collected in a movable receiving vessel, from which it is discharged by means of air pressure (gradually rising to 40 lbs.) into the specially constructed press; this reduces the moisture of the pressed yeast to 70%, leaves the yeast in excellent condition for pitching and furnishes a brilliant filtrate. The latter may be automatically returned to the fermenter without being exposed to air. The whole work can be completed in much less than 1 hr. from the time the yeast is skimmed. The process, intended for top-fermentations only, is illustrated by 14 cuts and diagrams.

L. W. HAAS.

Note on the starch-forming enzyme from malt. S. BORN. *J. Ind. Eng. Chem.* 7, 722(1915).—B. was unable to confirm the work of Davis (*C. A.* 9, 690) as far as the enzyme hemi-cellulase is concerned.
ISADOR MILLER.

The use of saccharometers for beers and for solutions of beer extracts. G. ROSSI. Rome. *Ann. chim. applicata* 3, 339-43(1915).—Continuation of expts. previously made (cf. *C. A.* 8, 3343), applied to beers and beer exts.
S. LEVY.

Note on the determination of original gravity. JULIAN L. BAKER AND F. E. HULTON. *J. Inst. Brewing* 21, 389-91(1915).—In the course of the authors' practice they found that in the case of beers which filter with an ordinary degree of freedom there is no appreciable loss of alc. even when the funnel is uncovered, but with waste beer, "bottoms," etc., which frequently contain a large amt. of sediment (hop sludge and finings), the filtration is often very difficult and protracted, and the loss of alc. in such cases is serious unless suitably protected.
L. W. HAAS.

Reducing original gravity of beers. P. PETIT. *Brewer and Malster* 34, 69-71; through *J. Soc. Chem. Ind.* 34, 628(1915).—With certain waters, *e. g.*, those rich in CaSO_4 and contg. little or no alkali carbonates, those contg. large amts. of Na_2SO_4 , and those which introduce a considerable amt. of iron into the wort, the original gravity of the wort cannot be reduced without the beer becoming thin and flat; waters rich in organic matter are particularly undesirable, owing to the presence of iron. Waters rich in NaCl and CaCl_2 and sufficiently calcareous are favorable to "body" and mellow-ness. Malts of long acrospire, friable and mellow, low-cured and moist, are not suitable for brewing full-bodied beers at low original gravities (the malt must be sharply kilned and employed in a thoroughly dry condition). Very mellow malts are preferably premashed at a high temp. (60-62°) and mashed quickly. Malts with a considerable proportion of steely points are best treated by preliminary acidification of the mash. The subsidiary acid mash should be added when the main mash has reached 60-62°. This eliminates bottom yeast cells, and also facilitates clarification of raw grain worts and improves the stability of the beer. For a full-bodied beer the most valuable dextrans are not those produced by slow saccharification of raw grain below the final mashing temp., but those produced between 65 and 70°. It is most important to boil sharply and the hops should be added after the wort has boiled for 15 to 30 min. Contact with air operates against fullness of body.
L. W. HAAS.

Experiments and experiences with sucrose as partial barley-malt substitute in the production of beer. AD. CLUSS AND VIKTOR KOUELKA. *Allgem. Z. Bierbrau.-Malzfabrikation* 43, 167-70, 173-8, 181-2, 189-91, 201-4, 209-13(1915).—The authors investigated the amt. of sucrose suitable to partially substitute malt, influence of sucrose on the compn. of wort, yield of ext., final degree of fermentation and character of final product, further means of regulating degree of fermentation, and proportion of hops best adapted to "sugar" beers. The extensive exptl. work (conducted on both lab. and practical scales) cannot be abstracted briefly; it led to the general conclusion, that even with a foregoing substitution of sugar for malt, there may be produced beers, which are free from objection and are fit to satisfy the demand of the consumer in every way.
L. W. HAAS.

Composition of beer wort prepared from malt and sucrose. ED. MOUFANG. *Allgem. Z. Bierbrau.-Malzfab.* 43, 191-4(1915).—By joint employment of malt and beet sugar (the proportion of the latter detd. by degree of modification and character of malt) a better yield (0.8-2%) was obtained. It makes a difference whether the sugar is added at the start of the mash or only after the wort is run off. Co-mashing of sugar increases the amt. of total as well as of non-coagulable protein substances. Sugar also effects perceptible differences as to assimilable N. Sugar-malt worts are

brighter and finer than pure malt worts and the final product of fermentation differs from pure malt beers as to total amt. and kind of fermentable substances.

L. W. HAAS.

U. S., 1,145,332, July 6. F. PAMPE. In rectifying alcoholic liquors, in a column still, steam is injected into the zone where the fusel oil is about to dissolve but is still substantially undissolved so as to form a whirling layer of mixed steam and fusel oil vapors and this mixt. is discharged from the still.

U. S., 1,146,139, July 13. J. F. DORNFELD. **Malting apparatus.**

U. S., 1,146,171, July 13. W. O. KAISER and G. F. STROEBEL. A non-alcoholic beverage is made by fermenting a mixt. of ext. of malt, cereals and hops with yeast and boiling the mixt., after fermentation, to rupture the yeast cells and dissolve their contents in the liquor and volatilize the alc.

U. S., 1,146,363, July 13. N. STATHAM. A catalytic material for oxidizing and purifying distilled spirits is made by carbonizing the woody material obtained in making pulp by the NaOH process. The product thus obtained is very porous (containing 85% of voids in some cases) and serves as an efficient carrier of O when the liquor is filtered through a tall column filled with it.

U. S., 1,146,793, July 20. M. HESSBERG. **Brewing.** The bittarn and hop resins are extd. from the residue and dregs obtained from a brew after cooling by mashing in the succeeding brew.

U. S., 1,147,767, July 27. A. VON LASZLOFFY. **Making cattle food and by-products from distillery slop** by concg. to a sirupy consistency and extg. with alc. to ppt. the albumins, dextrin, gums, etc., which are used for stock food.

U. S., 1,147,768, July 27. A. VON LASZLOFFY. **Lactic acid, succinic acid and fats from distillery slop** are recovered by acidifying, evapg. *in vacuo* a portion of the H₂O, treating with ether to dissolve fats and organic acids but not glycerol, sepg. the soln. and recovering its constituents in any desired manner. The slop may be given a preliminary fermentation treatment with lactic acid bacteria.

U. S., 1,147,769, July 27. A. VON LASZLOFFY. **Recovering lactic and succinic acids from distillery slop.** The gummy and albuminous constituents are eliminated from the slop by adding alc. and the remaining slop is treated with ether or other solvent which will dissolve the organic acids but not the glycerol, the soln. is sepd., concd. by evapg. the solvent, the pptd. fat is sepd. and the remaining soln. is allowed to crystallize to obtain succinic acid, leaving the lactic acid in soln.

U. S., 1,147,770, July 27. A. VON LASZLOFFY. **Recovering lactic and succinic acids and other by-products from distillery slop** by treatment of the slop with ether or other solvent which will dissolve the fat and lactic and succinic acids but not the glycerol, sepg. the soln., treating the residue with alc. and sepg. the soln. of ether and glycerol thus obtained.

U. S., 1,148,938, Aug. 3. J. TAKAMINE. **Moyaashi.** See Fr., 456,391 (C. A. 8, 2026).

Brit., 23,003, Oct. 11, 1913. C. REITER. **Non-alcoholic or practically non-alcoholic beers** are prepd. by acidulating the wort or mash by means of lactic acid or other acid-forming bacteria, or acids such as lactic, citric, and tartaric, or other chemicals, adding hops or their equivalent, pasteurizing, fermenting to a slight extent, if desired, again pasteurizing, chilling, and finally bottling. The beer may also be further pasteurized after bottling. Acids, etc., having a beneficial effect upon the bacteria may be added to the wort.

Brit., 6,519, Mar. 14, 1914. R. BLUM. Fermentation is influenced by exposing the liquid undergoing fermentation to radiations from a porous body, such as a clay plate, treated with a metal colloid, such as colloidal Au, Ag, or Pt prepared by the methods of Bredig or Svedberg, and a vegetable ext. such as aq. ext. of *Melissa officinalis* or *Phellandrium*. The clay plate may be suspended in a bottle above the fermenting liquid.

Brit., 6,775, Mar. 17, 1914. F. THATCHER and L. M. STILES. Alcohol is prepared from cactus plants, such as sotol (*Dasyliirion wheeleri*), napal (prickly pear), opuntia, cholla, sechugilla (*Agava lechugilla*), *Cereus giganteus*, *Echinocactus breconhotus*, etc. The cactus plants are ground and treated in a digester with superheated steam. The vapors are allowed to escape in order to remove HCOOH, etc. The liquid is filtered and fermented with a pure culture of *Saccharomyces cerevisiae* which has been grown in a mash of rye and malt containing NH_4 phosphate. The solid residue is dried for use as a food for animals.

Brit., 7,456, Apr. 18, 1914. E. W. KUHN. In brewing the malt is repeatedly treated with H_2O at about 10° to ext. the saccharifying enzymes, is then introduced into H_2O at 50° to peptonize the albumin, is boiled to gelatinize the starch, and is finally treated, during agitation, with the first ext. at 80° , to convert the starch into dextrin by the action of amylase only. H_3PO_4 may be added to the malt, and pepsin and amylase during the treatment at 50° and 80° , resp. Cf. C. A. 8, 3343.

Ger., 283,177, Oct. 31, 1913. VERSUCHS- UND LEHRANSTALT FÜR BRAUEREI. Removing the unpleasant taste from yeast by neutralizing it, before drying, by means of alkali (NaOH , Na_2CO_3 , $(\text{NH}_4)_2\text{CO}_3$, etc.), without washing, before or after the treatment. In this manner the cost of manuf. is lessened, and the loss of the product, due to washing, is avoided. Care must be exercised, in neutralizing, not to add the alkali in excess, since this would result in a change in the yeast substance. The drying of the neutralized yeast is effected in the usual manner.

17. PHARMACEUTICAL CHEMISTRY.

M. I. WILBERT.

Albert Plaut. M. C. WHITAKER. *J. Ind. Eng. Chem.* 7, 715-6(1915).—Obituary. ISADOR MILLER.

Micro-reaction of brucine. J. SCOTT. *Chem. and Druggist* 86, 145-6(1914).—Under the microscope brucine appears in semi-cryst. shapes, many of which are opaque; when put in water they sep. with fuzzy edges. On sublimation at about 150° brucine cracks during cooling, forming structures resembling trees and branches. At 185° a filigree is obtained. When CH_2I_2 is added to an alc. soln. groups of roseted needle-tufts of methylbrucine iodide are formed. Strychnine does not interfere. Brucine differs from strychnine in that a soln. of acetate with NH_4OH gives needle crystals (in excess of reagent this fails) and it is pptd. by CO_2 and OH but not by CrO_7 . HNO_3 produces a scarlet color, changing to blood-red, then yellow-red, and yellow; in water with HNO_3 soln. rosets of yellow, transparent, rectangular prisms are formed. When the soln. is dild. abundantly with H_2O , yellow specks of kakotelin separate, insol. in H_2O , sol. in dil. acids and crystallizable from dil. HCl and HNO_3 . To a HNO_3 soln. of HgNO_3 add some of the kakotelin and warm; a carmine color is produced. With Cl brucine gives red colors, which turn yellow when neutralized by NH_4OH . J. GAUB.

A new adulterant of essence of bergamot. E. COEN. *Ann. lab. chim. cent. dello Gabelle* 7, 89(1914); through *Ann. chim. applicata* 3, 372(1915).—The product is a

mixt. of 70% triacetin, 20% essence of bergamot, and 10% essence or terpenes of orange. C. proposes as test a modification of Schimmel's method: 10 cc. of the essence are agitated with 40 cc. of 10% EtOH, the liquid evapd. to a small vol., neutralized and saponified with alc. KOH, the whole evapd. to dryness, the residue extd. with Et₂O-EtOH mixt., and the ext. treated with KHSO₄. In presence of glycerol esters, there are given off in the cold vapors of AcOH, and in the hot vapors of acrolein (detectable by Rimini's reaction). S. LEVY.

Detection of camphor oil in essence of turpentine. E. COEN. *Ann. lab. chim. cent. delle Gabelle* 7, 99(1914); through *Ann. chim. applicata* 3, 372(1915).—The reactions of Utz, Halphen-Grimaldi, and Herzfeld are not always decisive for the detection of light camphor oil in essence of turpentine, and for distinguishing between that oil and pine oil. C. proposes as a test the detection of safrole, a component of camphor oil (it is found in only very small quantities, however, in certain special light camphor oils). He distils 100 cc. of the sample, and to the last 5 cc. of the distillate adds conc. H₂SO₄ drop by drop while cooling, and pours the mixture into 20 cc. H₂O, and exts. with 10 cc. amyl alc. On shaking the alcoholic layer with 5 cc. 20% KOH, the presence of safrole is indicated by a green or bluish color, passing into red on addition of H₂SO₄. S. LEVY.

Studies in synthetic drug analysis. IV. Estimation of phenacetin and salol in admixture. W. O. EMERY, G. C. SPENCER AND C. C. LE FEBVRE. *J. Ind. Eng. Chem.* 7, 681-4(1915); cf. *C. A.* 8, 3218, 3617; 9, 1972.—Two methods are given. The first employs acid hydrolysis; only the phenacetin is detd., the salol being found by difference between the wt. of phenacetin and the wt. of salol + phenacetin found by the usual procedure. The second employs alk. hydrolysis; in it both constituents are detd. directly. In the first, the phenacetin is converted into phenetidine sulfate and AcOH, the salol being partially volatilized during digestion. The phenetidine sulfate is freed from adhering salol by its insolubility in CHCl₃ and then re-converted into phenacetin by Ac₂O and NaHCO₃. In the second case (alk. hydrolysis) the salol is first converted into sodium salicylate and phenolate from which the phenacetin is easily separated and recovered by extn. with CHCl₃. The salol is then treated in rotation with Br soln. (excess), HCl, KI, and Na₂S₂O₃. Titration of the I liberated by the unexpended Br affords sufficient data for the estn. of salol. Explicit directions are given. ISADOR MILLER.

Study of civet. ERWIN SACK. Riedisheim. *Chem. Ztg.* 39, 538(1915).—S. gives a method of isolating a colorless oil which easily solidifies to a crystal mass, m. 32.5°, b₇₆₀ 342°, which he calls "civetone." Analysis gives the formula C₁₇H₃₀O, differentiating it from Walbaum's "muscone," C₁₅H₂₈O. Cf. *C. A.* 5, 762; 6, 2285. J. H. MOORE.

Substances which mask the color reactions of strychnine. EFISIO MAMELLI. Pavia. *Boll. chim. farm.* 53, 366-9(1914).—M. has studied the influence of various compds. employed in therapeutics on the Otto (violet striations of a H₂SO₄ soln. of the alkaloid in contact with crystals of K₂Cr₂O₇) and Mandelin (bluish violet coloration with a H₂SO₄ soln. of NH₄ vanadate which changes to reddish violet and finally to red after standing or addition of H₂O) color reactions. The tests were usually made with a H₂SO₄ soln. of strychnine to which varying amts. of H₂SO₄ solns. of the compds. in question were added. Phenacetine, *p*-phenetidine, *p*-aminophenol, phenocoll, salacetol, pyrocatechuic acid, aminomethylenepyrocatechol, dormiol, guaiacol, eucol, heroin, helmitol, pyramidone, Zn sulfophenate, glycerol and HCl are each capable, when present in considerable amt., of completely inhibiting both the Otto and the Mandelin color reactions; in smaller amts. these substances either diminish the intensity

of the colorations obtained or render them less definite. PhOH, anisole, phenetole, β -naphthol, betol, benzonaphthol and dulcin, even in small amts., prevent the recognition of strychnine by means of the Otto and Mandelin reactions. Acetylacetone and salol, when present in small amts., prevent the recognition of strychnine by the Otto reaction, but only mask the Mandelin reaction when present in somewhat greater amts. (a green coloration is then produced in the latter reaction). If strychnine is present in excessive amt., the above green coloration is replaced by a violet coloration which then yields the usual variations of reddish violet and reddish brown tints. PhNH_2 , AcOH, tartaric acid, stovaine and urotropine do not interfere with the Mandelin reaction, but render the Otto reaction less definite and completely mask the latter when present in excessive amts. *o*-Toluidine and Zn lactate mask the Otto reaction and diminish the intensity of the Mandelin coloration; quinoline and certain terpenes have a similar effect and render the latter coloration fugitive so that the usual variations in color are not presented. Piperonal, lecithin and papain have practically no influence on the Otto reaction and only effect a slight modification of the violet coloration of the Mandelin reaction. Antipyrine, aspirin, menthol, analgene, apolisine and salicylic acid interfere with the Otto reaction when present in preponderant amts. (as compared with the amt. of strychnine); they cause a fugitive bluish green coloration with the Mandelin reagent (salicylic acid causes a stable dirty green coloration). Quinine, euquinine, glucose, mannitol and citric and piperonylic acids either modify or mask the characteristic reactions of strychnine when present in excessive amts. The red striations which the anilides (acetanilide, benzanilide) give with $\text{K}_2\text{Cr}_2\text{O}_7$ crystals may be readily distinguished from the violet striations produced by strychnine. On the whole, phenols and aromatic amines and their derivs. show the greatest tendency to interfere with the characterization of strychnine by means of the Otto and Mandelin reactions, although this cannot be given as a general rule. Of all the substances employed in therapeutics which were investigated only caffeine, theobromine, saccharin, saligenin, sulfonal, trional, tetronal, veronal and antithermin were without effect on both the Otto and the Mandelin reactions. The variation in solubility of the compds. which mask the color reactions of strychnine affords an opportunity of sepg. the latter from a mixt. before applying the characteristic tests. A favorable procedure consists in extg. the mixt. under exam. with CHCl_3 , evapg. the CHCl_3 soln., drying the residue in a desiccator and washing the dry residue several times with anhydrous Et_2O ; in this way most of the substances mixed with the strychnine are eliminated and the latter remains undissolved. The color reaction of strychnine in a mixt. with phenacetin and phenetidine was rendered distinct by preliminary and repeated washing of the mixt. with warm H_2O . Any method of sepn. must be varied, however, to suit the circumstances.

H. S. PAINE.

Bismuth subnitrate. BILHANT. *Boll. chim. farm.* 54, 389-90(1915).—The following mixt. is used for impregnating a gauze which is used as a substitute for the usual iodoform gauze: 60 g. magistery of Bi, 60 g. neutral glycerol, 1000 g. boiled H_2O . The magistery of Bi is first mixed with the glycerol and this mixt. is then dild. with the boiled H_2O with stirring. The H_2O should be added at a temp. of about 40° so as to obtain a finely divided emulsion in which it is sufficient to immerse the gauze several times; the gauze is then wrung, dried, cut into the desired dimensions and finally sterilized by heating. This form of gauze has the advantage of being softer than iodoform gauze and is also inodorous, non-irritant and economical.

H. S. PAINE.

Hematoxylin as indicator in titrating alkaloids. H. P. *Svensk Farm. Tidskrift* 19, 336 (1915).—Defense of the Pharmacopeia in reply to criticism of Frerichs and Mannheim (*Arch. Pharm.* 235, 117). Based on *Pharm. Germ.* and *Pharm. Helv.*, H. P. suggests close adherence to the following procedure in titrating for quantities

of the cinchona alkaloids with HCl using hematoxylin as indicator: Warm 2.5 g. ground bark, 2.5 g. HCl and 20 cc. water in a covered dish on the water bath for 10 min. Then let stand 1 hr. and add 25 g. CHCl_3 and 50 g. Et_2O , shake and add 5 g. 15% NaOH soln.; shake occasionally for 10 min. and add 10 g. powd. tragacanth, shake vigorously and filter. To an aliquot (2 g. sample) add a few grains of sand and 10 cc. alc. and evap. until odor of CHCl_3 can no longer be detected. Now add 10 cc. alc. and warm to dissolve; then add 10 cc. water and a few drops of the indicator (alc. soln. of hematoxylin 1:100) and titrate with 0.1 N HCl to a brownish red; add 50 cc. water and again titrate to just yellow. One cc. of the acid is equiv. to 31 mg. alkaloid. The indicator need not be freshly prepared.

A. R. R.

Two compounds of emetine which may be of service in the treatment of entamebiasis. A. G. DU MEZ. *Philippine J. Sci.* (B) 10, 73-9(1915).—A review of the history, chemistry and pharmacology of ipecac, with the suggestion that emetine mercuric iodide and emetine bismuthous iodide be used in the treatment and also in the prophylaxis of entamebiasis. Emetine mercuric iodide is prepared by pptg. an acidified aq. soln. of emetine hydrochloride with Mayer's reagent, collecting, washing the ppt. with water and drying in the air at a temp. below 50° . Emetine bismuthous iodide is prepared in a similar way by the use of Dragendorff's instead of Mayer's reagent. Theoretically these compds. should be decomposed only slightly in the stomach but should liberate emetine in the intestinal tract. The compds. may be given in doses of 0.03 g. without causing nausea or vomiting.

M. I. W.

Standardized colored fluids (ARNY) 7.

Brit., 8,690, Sept. 5, 1913. BADISCHE. 3,3'-Dinitro-4,4'-dichlorobenzophenone is prepd. by nitrating 4,4'-dichlorobenzophenone with nitrating acid containing 44.5% of HNO_3 , and while maintaining the temp. between 0 and 10° . 3,3'-Dinitro-4,4'-diaminobenzophenone is prepd. by heating the above-mentioned chloro deriv. with alc. NH_3 . 3,3'-Dinitro-4-chloro-4'-aminobenzophenone is obtained, mixed with the 4,4'-diamino deriv., when using aq. instead of alc. NH_3 .

Brit., 21,134, Sept. 18, 1913. CHEM. FABRIK GRIESHEIM-ELEKTRON. Acetylene hydrogen halide addition products are obtained by the combination of C_2H_2 with H halides in the presence of Hg salts; the Hg salt may be in solid or liquid form, or dissolved or suspended in an appropriate medium, such as H_2O , HOAc , acetone, methyl ethyl ketone, etc. The reaction is effected at a suitable temp. and at ordinary or increased pressure; excess of either of the gases may be used. When solid Hg compds. are employed, the mixed gases may be led over the catalyst; when the Hg compds. are employed, dissolved or suspended in liquids, the two gases may be introduced into the catalytic liquid at two different points, so that the gases are not directly in contact. According to examples, mixts. of vinyl bromide and ethylidene bromide are obtained by passing C_2H_2 and HBr gas over coke impregnated with HgBr_2 ; vinyl chloride is obtained by passing C_2H_2 through aq. HCl containing HgCl_2 .

Brit., 8,153, Mar. 31, 1914. CHEMISCHE FABRIK VON HEYDEN AKT.-GES. Organomercuric compounds of aminoarylsulfonic acids, stated to be of therapeutic value, are obtained by heating mercuric salts of aminoarylsulfonic acids, or the acids together with compds. capable of forming mercuric salts thereof, until the products are sol. in alkalis. Products are specified from metanilic acid, aminophenolsulfonic acids, and aminosulfobenzoic acids.

Brit., 8,589, Apr. 4, 1914. H. MARTIN. To obtain lecithin from egg-yolk the

yolk is treated with hot alc. or other substance, which is then removed, as by distn. The prepn. is made into biscuits, sweetmeats, etc., with flour, sugar, cocoa, vanilla, etc.

Ger., 282,491, Mar. 1, 1913. O. GERNGROSS. In mfg. *N*-acyl derivatives of the imidazole series, halides of organic acids are allowed to act on the soln. or suspension of imidazole, its homologs, analogs, or derivs. in a solvent, in such manner that the halogen hydride acid resulting from the reaction is combined with an excess of the imidazole itself or with another base. Pyridine or quinoline or even inorganic bases are specified as suitable for this purpose. The resulting *N*-acyl derivs. are applied therapeutically; they are less poisonous than the non-acylated derivs.

Ger., 282,531, Apr. 26, 1914. CHEM. FABRIKEN V. WEILER-TER-MEER. In extracting reduction products of aromatic nitro compounds from aq. solns., the original nitro compds. are used as extrn. agents. *E. g.*, 1000 parts of a warm satd. aq. *p*-toluidine soln. are shaken, for a long time, twice with 200 parts of molten *p*-nitrotoluene. The extrn. is completed when the aq. soln. still contains about 0.02% *p*-toluidine.

Ger., 282,567, Mar. 31, 1914. CASSELLA & Co. Mfg. tetrachlorotoluene from PhMe, with the use of Fe or anhydrous FeCl₃ as carrier, by conducting Cl over the surface of the liquid, first with cooling to 12–15° and stirring, and then, after conversion into Cl₃C₆H₂Me, increasing the temp. gradually to 35–50° so that the mass just remains liquid.

Ger., 282,568, Nov. 7, 1913. BADISCHE. Mfg. aromatic amines from the corresponding nitro compds. by catalytic reduction with H or gases containing H, in the presence of Cu. Cu obtained by reduction from its salts, by heating in reducing gases such as CO or H below a red heat, is preferred. The reduction proceeds spontaneously in the presence of activators such as alkali compds. or metal oxides (MgO, Al₂O₃).

Ger., 282,611, Mar. 6, 1914. F. HOFFMANN-LA ROCHE & Co. In mfg. arsenic compounds of phosphatides or substances containing phosphatides, these substances are treated in organic solvents with H₃AsO₄, with heating, and the As compds. are sepd. in the usual manner, as in obtaining lecithin and other phosphatides. The products, on account of their solubility in the various solvents and the ease with which they may be emulsified, are used to supply As to the body in a readily assimilable form. They are applicable therapeutically.

Ger., 282,914, June 20, 1913. E. BENARY. Mfg. thiophene derivatives by allowing alkali hydrosulfides to act on haloacylaminocrotonic acid ester and haloacylalkylaminocrotonic acid ester. *E. g.*, Et 3-hydroxy-5-thiitolene-4-carboxylate is obtained from 100 g. Et chloroacetylaminocrotonate, 200 cc. alc., and 200 cc. of about 33% aq. KHS soln.

Ger., 282,991, July 13, 1913. BAYER & Co. In mfg. hydroxy derivatives of aliphatic aromatic ethers, the homologs obtained by substituting the CH₃ groups of ethylene glycol by alkyl, or their derivs., are etherified at one point by phenols, their homologs or their substitution products. The new products are used as intermediate substances in the manuf. of pharmaceutical prepn., and directly for allaying pain.

Ger., 283,061, May 30, 1913. I. POLLAK. In mfg. diastase preparations, the extrn. and concn. are effected in the presence of reducing substances, the action being effected at about 40°. Otherwise, H₂SiO₄ or salts and derivs. of this acid or sulfoxylic acid, etc., may be added to the diastase exts. obtained in the usual manner, without previous evapn.

Ger., 283,163, Mar. 10, 1910. GEN. CHEM. CO. Acetic acid anhydride or other acid anhydrides are obtained from the salts of the particular acids and halogens, by allowing these salts to react with halogens and thiosulfate. In the case of Ac₂O, a yield of 90% of the theory is realized by this method.

Ger., 283,271, Apr. 6, 1913. FARBW. v. M. L. & B. Mfg. 4-aminodiphenyl-3-sulfonic acid and its derivs. substituted in the 4'-position, by first converting benzidine-3-monosulfonic acid, in finely divided form, with 1 equiv. of nitrite and dil. weak acid, into the monodiazio compd., and then substituting H, halogen, OH, or other groups, for the diazo group, in the known manner.

Ger., 283,305, Nov. 17, 1912. CHEM. FABRIK ACTIEN (v. E. SCHERING). Mfg. pyrrolidine derivatives by the interaction of acylated pyroracemic acid ester, BzH, and *m*- or *p*-substituted derivs. of PhNH₂. The products have diuretic action. Cf. C. A. 9, 1829.

Ger., 283,306, Feb. 4, 1914. F. RASCHIG. Mfg. 1,3-dimethyl-5-hydroxybenzene-4-sulfonic acid by treating Me₂(HO)C₆H₃ with concd. H₂SO₄ or other sulfonating agents. The product is exceptionally reactive.

Ger., 283,333, Oct. 21, 1913. BAYER & Co. Mfg. alcohols of the pyrrolidine series by treating pyrroles with alc. groups in a side chain, in acid soln., with H in the presence of a catalytic metal of the Pt group, preferably under pressure. The resulting alcs. are applied in the manuf. of pharmaceutical preps.

Ger., 283,334, Nov. 23, 1913. F. FRITZSCHE & Co. Mfg. *o*-hydroxyquinoline double salts by the interaction of polybasic acids (tartaric, citric, etc.), alkali hydroxide, and *o*-hydroxyquinoline, in such amts. that at least one valence of the polybasic acid is satd. with alkali. These non-poisonous *o*-hydroxyquinoline salts are applicable as pathogenic bactericides in the blood stream.

Ger., 283,414, Feb. 5, 1913. M. LANDAU. Mfg. water-soluble neutral copper succrates by dissolving Cu(OH)₂ in alk. solns. of bioses, neutralizing these solns. with dil. organic acids, and evapg. to dryness. The Cu succrate is sepd., by means of an organic solvent, from the admixed organic alkali salts. This neutral, water-sol. Cu product is applied therapeutically.

Ger., 283,448, Aug. 5, 1913. BAYER & Co. Mfg. cyanomethylbenzimidazole and its derivs. substituted in position 2, by the reduction of *m*-nitro-*p*-acylamino-benzyl cyanides in acid soln., and the treatment of the resulting 1-amino-2-acylamino-5-benzyl cyanide by the usual methods. The new compds. are valuable intermediate products in the manuf. of dyes and pharmaceutical preps.

Ger., 283,449, Mar. 6, 1914. Addition to 282,568 (*supra*). BADISCHE. In mfg. aromatic amines, employing a catalytic mass obtained from Cu salts with the addition of salts or oxides of other heavy metals (Fe, Ag, Zn). The reduction of Cu salts is effected before or after the addition of the heavy metal compds.

Ger., 283,512, Apr. 19, 1913. A. KAUFMANN. Amino alcohols of the quinoline series, applicable therapeutically in the treatment of malaria, are obtained by allowing reducing agents to act on aminoketones of the quinoline series.

Ger., 283,537, Mar. 11, 1913. VEREINIGTE CHININFABRIKEN ZIMMER & Co., G. m. b. H. The amines of the quinia alkaloids result from the reduction of the corresponding nitro products according to the usual methods. They find application in pharmacy.

Ger., 283,538, Sept. 2, 1913. BAYER & Co. Mfg. salicylic acid derivatives by acylating the OH group of salicylic acid, its homologs or nucleus substitution products, with hydroxy-acids, in which the OH group is esterified by an aliphatic or aromatic acid residue. The new products have the advantage over the known simple acyl salicylic acids in being less irritating, more palatable, and more readily sol.

Ger., 283,597, Apr. 8, 1913. E. EBLER. Calcium substitution products of aromatic amines are obtained by allowing CaH₂ to react upon primary or secondary

monoamines of the aromatic series or upon primary arylhydrazines, with the exclusion of H_2O and at an elevated temp. The new Ca compds. are exceptionally reactive compds. sensitive to air and moisture, and serve for the prepn. of new compds.

Ger., 283,616, May 30, 1913. I. POLLAK. Diastase preparations are obtained by neutralization of the resulting lactic acid by means of $CaCO_3$, if the malt is repeatedly extd. in the presence of $CaCO_3$, and the residue desugared at $65-66^\circ$. The clarified wort, after cooling, together with the previously obtained diastase exts., and the addition of small amts. of strong reducing substances, is evapd. *in vacuo* to a sirupy consistence.

Ger., 283,859, Mar. 28, 1913. H. W. KLEVER. In compounding a hair dressing, the soln. of castor oil in alc. used heretofore has the disadvantage of matting hair, particularly the finer hair of women, on account of the high viscosity of the castor oil. Instead of castor oil, or other oils not sol. in alc., the esters of oleic acids or their derivs., as ricinoleic acid, with monohydric aliphatic alcs., are employed. The esters are dissolved in alc. and can be employed in that form as a cosmetic. A small amt. of β -naphthol, resorcinol, salicylic acid, or similar agent, can be added to this soln. The esters of oleic acid, especially the Me, Et, *n*-propyl, *i*-propyl, *n*-butyl, *i*-butyl esters, are freely sol. in 90% alc. *E. g.*, 13 parts Et oleate, $b_{11} 195-210^\circ$, are dissolved in 100 parts 90% alc. The viscosity is much less than that of castor oil, so that the hair does not mat.

Ger., 283,860, Aug. 28, 1913. Addition to 283,859 (*supra*). H. W. KLEVER. In the manuf. of a hair dressing, properties similar to those of the products specified in the principal pat. are exhibited by the esters of monohydric hydroaromatic alcs., as well as the mono- and di-esters of trihydric alcs. of a fatty, hydroaromatic or aromatic character. These esters are generally sufficiently sol. in alc. or liquid. If an ester is cryst., it is mixed with others of the specified esters to obtain a product sol. in alc. and of sufficient fluidity. *E. g.*, cyclohexanyl and menthyl oleates are liquid fats which are sol. in 96% alc. to the extent of 5%. The same is true of the phenyl or cresyl oleates, whose tendency to crystallize is overcome by the addition of some cyclohexanyl or ethyl oleate. Also, suitable products consist of a mixt. of mono- and diglycyl oleate (obtained by heating ethylene glycol and oleic acid), and of a mixt. of mono- and diglyceryl oleates. The terpinol, resorcinol, pyrocatechol, guaiacol, and phloroglucinol esters of oleic acid, and the like, which are crystalline at the ordinary temp., yield with Et oleate fluid fats sufficiently sol. in alc. The unsatd. fatty acids can be substituted, in the esters, by the satd. fatty acids, especially by those in which the C chain contains less than 18 C atoms.

Ger., 284,003, July 11, 1913. F. L. HAHN. Mfg. oxygen baths by decomp. persulfates in the presence of other per-salts, such as perborate or percarbonate, or of H_2O_2 , if necessary in the absence of carbonates, by means of catalyzers. The reaction temp. can be depressed by very small amts. of catalyzers to the temp. of a warm bath, about 40° . The known organic catalyzers can be employed, also the metals of the Pt group, as well as all metals which can exist in several stages of oxidation, such as Fe, Mn, Cu, Ce, etc. They can be applied dissolved, colloidal, or in fine suspension, sep. and in mixts. The action of some of these catalyzers is greatly increased by the addition of small amts. of NH_4 salts. Suitable therapeutic or cosmetic additions may be made to the baths. Since by the decomp. of the persulfate, acid is liberated, mixed $O-CO_2$ baths can be made by the addition of carbonates, or directly by employing percarbonates.

Ger., 284,148, Feb. 5, 1915. F. HOFFMANN-LA ROCHE & Co. Isolating the active constituents of the pituitary body in a H_2O -sol. form suitable for injection.

Exhaustive clinical expts. have shown that all of the active substances of the pituitary ext. are readily sol. in abs. alc. In the treatment with abs. alc., admixts. of inactive albuminous substances (albumoses and amino acids) remain undissolved, together with inorganic constituents. From the abs. alc. soln., the chlorides of the active pituitary substances sep. in cryst. form upon the addition of pure anhydrous ether. By repeated pptn. with abs. ether, completely purified compds. can be secured. The sulfates can be prepd. from the hydrochlorides by substituting alc. H_2SO_4 for the alc. HCl . The resulting product is nitrogenous, and dissolves readily in H_2O and alc. With mineral acids, cryst. hygroscopic salts are obtained. The N-content is 10.80%. *E. g.*, 1 kg. of an aq., albumin-free pituitary ext., is evapd. *in vacuo* to dryness. To the soln., obtained by extg. this residue for about 15 mins. with 50–100 cc. abs. alc. at the ordinary temp., are added 200–400 cc. abs. ether, whereupon the active substances ppt. By repeated soln. in abs. alc. and pptn. with abs. ether, the product is rendered perfectly pure and colorless.

18. ACIDS, ALKALIES, SALTS AND SUNDRIES.

T. LYNTON BRIGGS.

Composition of the salines of the United States. IV. A correction. J. W. TURRENTINE. *Bur. Soils. J. Ind. Eng. Chem.* 7, 687–9(1915).—Table of corrections to the analyses of C. A. 7, 870. ISADOR MILLER.

The potash situation. E. HART. *J. Ind. Eng. Chem.* 7, 670–1(1915).—A brief account of the various suggestions which have been made for the relief of the potash situation with emphasis on Hart's process, about to be introduced technically. In this a mixt. of feldspar refuse and BaSO_4 is heated in a reducing flame producing a Ba Al silicate (36% SiO_2). This is run into H_2O while molten and the granulated material ground and floated. The paste is treated with H_2SO_4 , yielding a soln. of alum and $\text{Al}_2(\text{SO}_4)_3$ and a solid residue of $\text{BaSO}_4 + \text{SiO}_2$. The latter can be used as a substitute for China clay. The soln. yields K alum on evapn. and from this K_2SO_4 can be prepared. ISADOR MILLER.

The potash situation. SAMUEL H. DOLBEAR. *Met. Chem. Eng.* 13, 481–2(1915).—Because of the embargo placed on German exportations the situation is becoming acute. In the Searles Lake region, Cal., which consists of 40,000 acres of placer claims, the problem consists in sepg. KCl from solns. of NaCl , Na_2SO_4 , $\text{Na}_2\text{B}_4\text{O}_7$ and other salts. Litigation and difficulty in perfecting processes delay supplies from this source. A plant has been erected at Agnew, Cal., to ext. potash from "vinasse" or distillery refuse. At Point Loma, Cal., a plant has been erected to treat kelp, which contains, dry, 15% K_2O . In Alsace, deposits 6–30 ft. thick covering 7 sq. m. estd. at 1,500,000,000 tons of salts have been discovered. The future possession of the province will det. whether the product will compete with that of the German trust. Barcelona and Lerida, provinces in Spain, contain undeveloped deposits. H. L. OLIN.

Potash deposits in Spain. C. B. HURST. *Commerce Reports* No. 188, 739(1915); cf. C. A. 9, 2431.—A discussion of the attitude of the Spanish government with reference to the working of these deposits. E. J. C.

Substitutes for materials seized (in Germany) in the interest of defence. GARLEPP, STABY, NALLINGER, OVERATH, PICHLER AND WAHL. *Z. Ver. deut. Ing.* 59, 457–63, 478–85(1915).—The subject matter is the proceedings of the Mannheim section of the Verein deut. Ingenieure. The topics of the discussions were the necessity of substitutes for bearing metals; better service from and substitutes for lubricating oils; substitutes for benzine for power purposes, petroleum for illuminating purposes,

rubber and copper conductors; and the desirability of increasing the use of coke in order to obtain the by-products. Each subject is treated in detail by one of the above authors and followed by a discussion. The article cannot be briefly abstracted.

Destructive distillation of Pacific coast kelps (HOAGLAND) 22.

U. S., 1,145,897-8, July 13. H. HOWARD. Apparatus and method for making hydrochloric acid. NaCl is supplied from the receptacle 2 and H₂SO₄ from the receptacle 16 to the chamber 5 where the two are mixed in proper reacting proportions. The gas evolved is led off through the pipe 6 to an absorption system and the partially decomposed mixt. is continuously fed to the furnace 1 where the reaction is completed.

U. S., 1,147,832, July 27. F. VON KÜGELGEN and G. O. SEWARD. Aluminium chloride is made by mixing bauxite or clay with sufficient C to reduce compds. of Fe or Al, heating to

300-450° with Cl until the Fe is eliminated, and then treating with Cl at 900° in an other app. until the alumina is converted into AlCl_3 . Any Ti chloride formed is sepd. by volatilization.

U. S., 1,147,942, July 27. J. S. HEALY. Printers' blankets are formed of composite layers of felt, muslin or other fabrics impregnated with a mixt. formed of glue 4, glycerol 5, gum arabic 0.5, china clay 0.5, and CH_2O 0.015 part.

U. S., 1,147,969, July 27. G. PALMER. Printers' blankets are formed of layers of felt and rubber or canvas with an intervening layer formed of glue, glycerol, plaster of Paris and chicle, in the proportions of 8:2:2:2.

U. S., 1,147,991, July 27. L. VON JARACZEWSKI. Bone-black filtering material. See Ger., 268,881 (*C. A.* 8, 1861).

U. S., 1,148,092, July 27. H. T. KALMUS, W. L. SAVELL and K. B. BLAKE. Alumina is made by treating a mixt. of nephelite syenite with SO_3 and H_2O to form an unstable sol. compd. of alumina with SO_3 carrying some silica into soln., heating the soln. thus formed to 55° to drive off some of the SO_3 and ppt. the silica, sepg. the soln. and further heating it to 80° and agitating it to decompose the alumina- SO_3 compd. and ppt. alumina. Cf. *C. A.* 8, 1647.

U. S., 1,148,156, July 27. E. E. DOUGHERTY. Obtaining alkali and alumina from leucite. Sufficient H_2SO_4 is added to the leucite to combine with the bases and the mixt. is then heated with the further addition of about 2% its wt. of HCl until it becomes pasty and the greater part of the H_2O present has been driven off. Then the temp. is raised to 500° and the heating continued to drive off the HCl and remaining H_2O (the HCl being passed into a fresh charge which has been mixed with H_2SO_4); the H_2O -sol. sulfates are recovered from the residue by lixiviation.

U. S., 1,148,570, Aug. 3. C. BOSCH, A. MITTASCH, H. WOLF and G. STERN. A catalyst for the synthesis of ammonia from its elements consists of Fe 98% and Al_2O_3 2% and is capable of retaining its catalytic power for several weeks if not contaminated with contact poisons. It is made by melting Fe with Al_2O_3 in a current of O and then reducing in H at as low a temp. as possible. MgO, ZrO_2 , clay or Mo oxide combined with Fe also form efficient catalysts.

U. S., 1,148,850, Aug. 3. S. E. MELEMAN. Obtaining potash from siliceous minerals. Comminuted feldspar is mixed with C and NaCl, the mixt. is heated in a bath of concd. H_2SO_4 to 200° to partially decompose it and then roasted in air at 1000-1150° and the sol. K salts formed are recovered by lixiviation.

Brit., 12,142, May 24, 1913. W. PLINATUS. A plastic composition, resembling horn, ivory, or ebonite, is made by mixing albumins, such as serum or egg albumin or casein or conversion products thereof, with an ester of a polyvalent alc. of the fatty-acid series or derivs., such as the acetins or other esters of glycerol or polyglycerol. The esters of tartaric, lactic, glycollic, hydroxybutyric, formic, or acetic acid may be used, or those obtained by esterifying lactones, or anhydrides of the α -hydroxy acids. Other substances, such as fats and oils, or sulfuretted oils, resins, pitches, paraffins, camphor, cellulose derivs., or caoutchouc, may be added in a dissolved state or otherwise. The mixt. or finished product may be treated with hardening substances, such as aldehyde, tanning substances, or Cr compds., and coagulable albumins may be coagulated by chem. or steam treatment. Filling and coloring substances, such as metals, salts, asbestos, pumice, infusorial earth, and SiO_2 , may also be added. Cf. *C. A.* 8, 3378.

Brit., 15,090, June 30, 1913. P. DE BRÜNN. In the manuf. of zeolites by the wet method, very dil. solns. of the reagents (Na aluminate and Na silicate) are employed. An example mentions 6 lbs. Na_2SO_4 , 12 gals. H_2O , 844 cc. of a soln. of alumina contain-

ing 45.6 g. of Al_2O_3 and 315 g. of water-glass soln. at 45° Bé. containing 75 g. of SiO_2 . The ppt. is allowed to settle, the mother liquid is poured off, and the ppt. is washed and then pumped in a filter-press; or it may be washed in the filter. The cake is dried, broken up, and hydrated in hot H_2O . The mother liquor may be treated with an acid such as H_2SO_4 and made into a 5% soln. for use again; or more soda may be added so that it will form Na aluminate of the right concn. for use again when an Al salt is added. Cf. C. A. 8, 2915.

Brit., 17,731, Aug. 1, 1913. H. PLAUSON. Pure finely divided carbon is obtained from coal or wood charcoal by grinding it to a very fine powder, purifying by treatment first with H_2SO_4 or a mixt. thereof with HCl , washing with H_2O , treating with HNO_3 , again washing, treating with HF , and again washing, traces of acid, if desired, being finally removed by means of alkali; the product is then brought into colloidal soln., preferably in H_2O , by known methods, *e. g.*, by means of tannin, by trituration at high speed or under great pressure, as described in 17,729, 1913 or by the elec. current; natural colloids such as gelatin, casein, India rubber, albumins, etc., may be added to accelerate the process. The colloidal soln. is allowed to settle and is poured off, the residue being again treated as before; the C is then pptd. from the soln., by addition of acid or other electrolyte, and dried. It may be treated further in an atm. of H or N or *in vacuo* to carbonize any hydrocarbon present. The product is suitable for coloring purposes.

Brit., 17,732, Aug. 1, 1913. H. PLAUSON. Colloidal graphite is obtained from coke by bringing finely powdered coke into colloidal soln. in H_2O or other nonelectrolytic liquid, such as oil, kerosene, ligroin, etc., in known manner, or as described in 17,729, 1913, and 17,731, 1913 (*supra*). The graphite can be sepd. from the liquid by known means. The coke powder may be subjected to a preliminary purification with acids, followed by neutralization with alkalies and washing. The plasticity of the product may be improved by adding powdered clay or the like to the coke, so as to obtain a colloidal mixt. of graphite and clay, etc. Small amts. of natural colloids, aldehydes, tannin, W, or chromic acid, etc., may also be added to facilitate the process.

Brit., 19,924, Sept. 3, 1913. M. TÖFFER and P. MÜLLER. In a process of evaporating liquids, etc., the liquids, damp substances, etc., are sprayed in a finely divided condition into a chamber or passage, so as to form a flat layer of mist which is projected between two layers of drying-medium occupying almost the width of the chamber and moving closely above and below and parallel or slightly convergent on the layer and in the same direction; the process may be carried out at about 40° .

Brit., 23,541, Oct. 17, 1913. BADISCHE. Catalytic agents for use in the manuf. of sulfuric anhydride are prepd. by bringing vanadic acid, or a compd. thereof, on to a very finely divided, indifferent carrier, *e. g.*, finely ground pumice, the granules of which have a diam. of not more than 20 microns. The vanadic acid is pptd. on to the carrier from a suitable soln., optionally in the presence of other catalytic bodies; or the ingredients are merely mixed together, with or without binding agents, and, if desired, the mixt. can be formed into any suitable shape. It is advantageous to heat the catalytic agents for some time in gases containing SO_2 . Should the catalytic agent be hygroscopic, for instance, after heating in SO_2 , this property is removed by heating in the presence of air and in the absence of SO_2 . Alkali, either as such or as a salt, may be added to the catalytic agent to impart thereto stability against increase of temp. In examples, pumice powder with grains of the diam. of about 1 micron is mixed with NH_4 vanadate, and the mixt. heated first in air to drive off NH_3 and then in gases containing SO_2 ; kieselguhr or pptd. silicic acid is mixed with a soln. of K vanadate or NH_4 vanadate and KOH , or alkali carbonate, sulfate, or nitrate, and the mixt. granulated and afterwards heated in burner gases and, if desired, in air.

Brit., 7,866, Mar. 28, 1914. A. CLASSEN. Royal Technical University. Nitrogen pentoxide is prepd. synthetically by subjecting air in the presence of finely divided, conducting contact substances consisting of metal in a colloidal form to the simultaneous action of dark and sparking elec. discharges at a temp. substantially between 50 and 90°. The pentoxide is afterwards absorbed in H_2O or alkali lye. The colloidal contact substances are advantageously prepd. with the aid of gelatose, obtained by protracted boiling of a soln. of gelatin or bone or fish glue, although glue, albumin, and salt-like compds. of albumin may be used in the place of gelatose. This method is particularly suitable for the metals of the Pt group, the rare earth metals, Au, Ag, W, Mo, U, Ti, and Nb. The gelatose acts as a protective colloid for the soln. of the colloidal metal, and may be added before or after the production of such soln. In the case of Au, the gelatose acts as a reducing agent in a boiling soln. of a salt; while in the case of $PtCl_4$ soln., the reduction is effected in the presence of gelatose by, e. g., $N_2H_4 \cdot H_2O$. The colloidal soln. is concd. and treated with indifferent carriers, such as asbestos, saw-dust, or kieselguhr, which take up the colloidal metal. The mass is then dried, and may be afterwards calcined to convert Cr, Mo, W, Si, ferrochromium, ferrosilicon, or chrom-nickel into finely divided state, and after corrosion with acids or bases, it is treated in a ball mill with concd. gelatose soln. The liquid so obtained is used to treat indifferent carriers, such as asbestos. The oxides of U, Ni, W, etc., may be used as contact carriers, and they at the same time exercise contact effects.

Brit., 7,920, Mar. 28, 1914. W. FELDENHEIMER. A cleaning composition consists of olive-oil or other soap and killas, an argillaceous schist found in Cornwall, with or without essential oils. The killas may be obtained sufficiently fine by the process described in 4,155, 1907.

Brit., 8,015, Mar. 30, 1914. SIEMENS & CO. Rare earth salts, such as the fluorides, phosphates, tungstates, borofluorides, silicofluorides, titanofluorides, and other salts are obtained by treating a soln. of rare earth salts, for instance residues from Th manuf., opened-up monazite sands, cerite solns., and the like, with insol. or sparingly sol. precipitants, particularly Ca, Ba, Sr, Mg, and Al salts. Precipitants mentioned are fluorides and phosphates of alk. earths (particularly natural apatite and fluorspar), Ca tungstate, and K borofluoride, silicofluoride and titanofluoride. The ppts. may be rendered more dense by heating, particularly when intended as illuminating additions to arc-lamp electrodes.

Brit., 8,030, Mar. 30, 1914. BADISCHE. Removing carbon monoxide from gases by treating the gas, in Fe or steel app., with ammoniacal Cu_2Cl_2 solns. containing at least 60 g. of NH_3 per l., either as free NH_3 or as $(NH_4)_2CO_3$. The absorption is preferably effected under pressure; pressures above 100 atms. effect rapid absorption. The soln. can subsequently be freed from CO by evacuation, and re-used; the process may be made continuous by using 2 vessels which are employed alternately for absorption and evacuation; or the soln. may be circulated continuously, first through an absorption vessel, and then through an evacuation vessel. According to an example, a soln. containing Cu_2Cl_2 , NH_4Cl , and NH_3 is employed. The process is particularly applicable to the purification of H from small quantities of CO. Cf. C. A. 9, 2299.

Brit., 8,279, Apr. 1, 1914. H. E. WILKINSON and H. STEWARD. A lubricant for gear-boxes, etc., is obtained by adding 20.25% of flour to hot oil or grease and allowing the mixt. to cool slowly in a closed pan.

Brit., 8,462, Apr. 3, 1914. BADISCHE. Catalysts are prepared by treating with a compd. of a catalytic metal, a complex insol. compd. containing 1 or more easily replaceable bases, and of the type of the artificial zeolite, Na Al silicate. The catalyst

may be heated or subjected to reduction before use. In examples, Na Al silicate is treated with an acidified soln. of PdCl_4 or with $\text{Ni}(\text{NO}_3)_2$ soln., and the product reduced, giving a catalyst suitable for the hydrogenation or dehydrogenation of organic compds. or oils. Other catalysts may be prepared by treating the Na Al silicate with solns. of salts of Cu, Zn, or V, or with solns. of salts of several metals either simultaneously or successively. The catalyst obtained by treating Na Al silicate with HCl soln. of V chloride is suitable for use in the manuf. of SO_2 .

Ger., 275,343, June 13, 1914. F. HLAVATÍ. Mfg. compounds of nitrogen with hydrogen or oxygen, with the aid of contact substances. A mixt. of Ti with 1 or more metals of the Pt group is used as the carrier.

Ger., 277,054, July 20, 1914. F. HLAVATÍ. Addition to 275,343 (*supra*). Mfg. ammonia. See U. S., 1,079,705 (C. A. 8, 405).

Ger., 283,212, Mar. 1, 1914. F. RASCHIG. In the manuf. of nitric acid from KNO_3 and H_2SO_4 in chambers under reduced pressure, employing a heated vacuum pan, to which the mixt. of H_2SO_4 and KNO_3 is fed through a barometer tube, continuously, while the bisulfate flows out continuously through another barometer tube, the evolved HNO_3 , after condensation, flowing out through a third barometer tube in a uniform stream. A suitable app. is specified.

Ger., 283,444, Apr. 26, 1913. SUDENBURGER MASCHINENFABRIK UND EISENGIESSEREI, AKT.-GES. Process and app. for evaporating strongly foaming liquids, such as albuminous or oleaginous materials. The steam, laden with foam and liquid drops, is conducted through a jet separator with such speed that the bubbles constituting the foam are broken up and held by the walls of the jets, the steam issuing with but a few drops. The steam is then conducted, under much less pressure, to a disk separator, where the remaining liquid is sepd.

Ger., 283,447, Apr. 7, 1911. F. HLAVATÍ. Addition to 275,343 (*supra*). In mfg. ammonia from its elements, employing contact substances, such as Ti and Pt, in the proportions of their at. wts., *e. g.*, 48.1 parts Ti to 195.2 parts Pt, in admixt. The resulting amts. of NH_3 are uniformly greater than when these contact metals are used in other proportions. At high temps. the difference is not so great as at moderate temps. Practically twice the yield of NH_3 is secured with the use of the metals in equiv. proportions, as when they are used in equal parts. Cf. C. A. 8, 23.

Ger., 283,461, Dec. 2, 1913. A. GASSER. Mfg. a plastic mass from peat and wood by crushing peat and wood together in a wood-crushing machine. The product is used for packing and transporting fruits, meats, fish, storing fruit for the winter, also as an insulating layer and for holding moisture under flower pots, and the like.

Ger., 283,472, Jan. 21, 1913. F. W. BAKEMA. Machine for crushing and transporting superphosphate and like substances, with the employment of a rotary cutting drum similar in construction to a grass cutting machine.

Ger., 283,535, Apr. 12, 1914. Addition to 281,084 (C. A. 9, 1833). E. HERMAN. In the manuf. of nitrogen oxides by the combustion of air and C compds., according to the principal pat., the combustion gases are conducted through the combustion furnace in a current directed downwardly from above, and the gaseous products of combustion are drawn off through a cooling chamber below the reaction chamber, while the H_2O of condensation is drawn off from the lowest point of the cooling chamber. The CH_4 is first mixed with air of normal comp., and the enriching with O is effected in the reaction chamber. CH_4 and a part of the air are conducted in a number of currents, obliquely downwards, into the center of the reaction chamber, while the principal portion of the air is conducted through the reaction chamber centrally. Suitable constructional details are specified.

Ger., 283,395, Feb. 1, 1914. UNION-WERKE, AKT.-GHS., FABRIKEN FÜR BRAUEREI-EINRICHTUNGEN. App. for washing filter masses and the like. Cf. C. A. 8, 1892.

Ger., 283,790, Oct. 31, 1913. O. BRÜNLER. In a process and app. for the continuous evaporation of sulfuric acid, the acid is evapd. in Pb-covered or earthenware containers by means of an immersed flame, to about 62° Bé., whereupon it is conducted into an Fe container, in which the final concn. is effected by means of an immersed flame. As shown in the constructional details, the immersed flames act in auxiliary vessels, and the partially concd. acid is conducted from the bottom of the earthenware or leaden vessel where a test outlet is provided. The purpose of the preliminary concn. is to conc. the acid to such an extent that it will not attack the Fe vessel used in the final concn. where the higher temp. necessitates the use of this metal.

Ger., 283,824, Apr. 15, 1914. BADISCHE. Mfg. nitrogen oxides by the catalytic oxidation of NH_3 with air or O, with the employment of metals of the Fe group or their oxides as catalyzers. The addition of Bi or its compds. materially increases the catalytic activity of the specified agents. Binding agents may be added also, but metalloids compds. are to be avoided. The contact masses are best employed in the form of a layer of sep. pieces. E. g., a mixt. of 45 parts pure Fe or Mn nitrate and 1-2 parts of Bi nitrate is dissolved with the addition of pure HNO_3 . The pptn. is effected with NH_3 ; the ppt. is dried to some extent, formed into dice-shaped pieces, carefully heated, and then charged into a tube through which NH_3 and air are led. At about 700°, a yield of over 90% of N oxide is obtained. Such a contact mass can be made also by the oxidizing melting of a mixt. of pure Fe powder with 3% Bi_2O_3 , and subsequent grinding. Metallic Fe itself may be activated with Bi or its compds., and then introduced into the contact furnace. Cf. C. A. 9, 1673.

Ger., 283,894, July 16, 1914. HENKEL & CIE. Mfg. perborates by subjecting to autooxidation, amalgamated Al or Zn in aq. soln. of H_3BO_3 or alkali borates, in the presence of alk. earth hydroxide, especially $\text{Ca}(\text{OH})_2$, with continued introduction of O or gases containing O under increased pressure. A temp. of 0° is preferred. E. g., 0.5 part thin Al cuttings and 10 parts Hg are treated with 10 parts satd. borax soln. and 1 part $\text{Ca}(\text{OH})_2$. The reaction mixt. is maintained, in a pressure vessel, under a pressure of O of about 5 atms., and well stirred, with cooling, for 3 hrs. An Al Ca perborate with a content of active O of about 3.5% is pptd. in almost theoretical yield. The mother liquors are almost free of active O.

Ger., 283,956, July 13, 1913. P. FENAROLI. Mfg. nitrosyl chloride and its solns. or mixts. with Cl by allowing NO to act on gaseous Cl, evolved from liquid Cl, under increased pressure. NO and Cl can be simultaneously or alternately forced into a container. In the gaseous layer in the upper part of the container NOCl is formed; this dissolves immediately in the liquid Cl, with reduction of pressure. In consequence of the reduced pressure, a fresh amt. of Cl is volatilized; this combines with more NO until all Cl is converted, by further introduction of NO, into NOCl. The reaction can be interrupted earlier with a view to obtaining compds. which contain NO and Cl in other mol. proportions than 1:1. The solns. of the NOCl in Cl can be used, among other purposes, for bleaching flour. Quant. yields are obtained.

Ger., 283,981, Nov. 25, 1911. CHEM. WERKE KIRCHHOFF & NEIRATH, G. M. B. H. Mfg. stable mixtures of sodium perborate with tartaric or citric acid, by mixing a concd., strongly cooled, aq. soln. of the acid or of an acid salt thereof, with crystd. or more or less dehydrated NaBO_3 , and evapg. the resulting sirupy mixt. *in vacuo* at a low temp. There is no resulting decompn. of the perborate. The mass obtained

in vacuo is scarcely hygroscopic, but stable and solid. E. g., 150 g. pure tartaric acid are treated with 50 cc. H_2O , poured over it, and the whole is then cooled with a refrigerating machine. Then, with constant stirring, 320 g. crystd. $NaBO_3$ are introduced, in small amts., and the mass is stirred further until an almost clear, viscous mass results. A small amt. of O is evolved during this process. The mass is then filtered under pressure, and then either directly converted into the sirupy stage, or first evapd. *in vacuo* to such an extent that upon cooling it solidifies.

Ger., 284,043, Aug. 23, 1912. M. ULLMANN. Mfg. soluble fluoride by treating Na_2SiF_6 with alkalis. The Na_2SiF_6 is slowly charged into a heated alkali soln. in such amt. that the resulting alkali fluoride remains in soln. after the reaction is completed. A concd. soda soln. of known content of Na_2CO_3 is heated to about 100° , and into this soln. an amt. of Na_2SiF_6 corresponding to the reaction formula is introduced in small amts. in order to prevent foaming. The thin slurry is heated with stirring until practically all the CO_2 has escaped. The mass is then dild., heated, the ppt. allowed to settle, and the almost clear liquid decanted or filtered. If, on the whole, so much H_2O is employed as corresponds to the solubility of the entire amt. of NaF obtained, the clarified soln. contains the NaF in almost quant. yield. If less H_2O has been taken, then to the silicic acid residue can be added sufficient H_2O , with mixing and heating, to ext. the residual NaF. In this manner the enclosure by gelatinous silicic acid of undecompd. Na_2SiF_6 or of NaF formed, and its removal from the reaction mixt., are prevented. Also, the silicic acid is obtained in a form in which it can be readily sepd. from the liquid. In this manner a NaF soln. of about 5% is obtained, from which the fluoride can be recovered by evapn. Instead of dilg. after the conclusion of the reaction, the mass can be heated further until the mixt. is converted into a dry powder in which SiO_2 and NaF are mechanically mixed. The NaF can be dissolved simply by placing the mixt. in H_2O . The dry mixt. can be more readily transported, and in many cases can be employed instead of pure NaF.

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

The microscopic character of China clay. GEO. HICKLING. *J. Soc. Dyers, Colorists* 31, 70-4 (1915).—The extreme minuteness of particles of China clay has long delayed its microscopic study. Only 3 minerals, kaolinite, muscovite and quartz are present in appreciable quantities in China clay and after examining 5 typical analyses, and studying the sp. gr. of particles by introduction into a diffusion column of $CHBr_3$ and $CHCl_3$, H. states that the whole process of the conversion of feldspar into kaolinite may be described as consisting in the gradual extn. of the alkali and loosely combined silica, muscovite being an intermediate stage in the process. There are also indications of other intermediate stages and China clay may be described as consisting principally of the intermediate decompn. products from muscovite to kaolinite. The article contains photomicrographs and descriptions of samples of coarse and best China clay and of individual rouleaus of kaolinite.

dark blue lusters, solns. of organic Na compds. and organic boric acid compds. are added to the specified mixt. The resulting colors remain pure blue even at the highest temps., and resist wear. The organic Co, Zn, and Si compds. are dissolved in ethereal oils and then mixed with each other, and in like manner the organic Na and boric acid compds. Solns. of organic Co compds. can be obtained by incorporating Co(OAc) , in white American resin (colophonium) or in other resins at the m. p., obtaining thereby a Co resinate which is dissolved in ethereal oils. Co(OAc) is dissolved in alc. and this soln. is placed in hot resin-alc. soln. on the water bath, then the alc. is driven off by boiling and the residue is heated over a small free gas flame until a friable dry metal resin results which is dissolved also in ethereal oils. The solns. of the organic Zn and Na compds. are treated in the same manner. To prep. solns. of the organic Si compds. ethereal resin solns., ethereal oils or the like, SiCl_4 or like Si compds., are incorporated in cooled abs. alc., and the excess volatile constituent is driven off by continued boiling. Instead of alc., aldehydes, mercaptans, ketones, or unsatd. hydrocarbons may be used. To obtain solns. of organic boric acid compds., molten H_3BO_3 is heated in isobutyl alc. After distg. off excess alc. at 250° , a residue remains which is completely and readily sol. in ethereal oils and contains 12% H_3BO_3 . All other boric acid esters may be applied. Of the organic solns. of Co, Zn, etc., the content of inorganic oxide is detd., and the luster is made up accordingly. E. g., in 100 g. of a blue luster containing no Au, are contained 2.005 g. Zn, 4.625 g. SiO_2 , 3.235 g. CoO , 0.175 g. B_2O_3 , 0.300 g. Na_2O .

Process of imitating marble and other stones and majolica tiles and pottery by the application to glass of a comp. containing liquid and pulverized water-glass and a sol. tar color, consisting (1) in replacing the tar color by other colors or pigments so that ordinary marble pottery and glazed tiles can be more closely imitated, and (2) in applying heat to harden the comp. after its application.

Brit., 7,577, Mar. 25, 1914. W. GRIFFITHS. A road-paving block consists of irregular stone fragments united along the lines of contact by Portland cement in a

mold to form a rigid framework and then immersed in a heated condition in molten pitch or the like sufficiently long for the molten pitch to penetrate into the interspaces between the fragments, these interspaces communicating with each other and with the outer faces of the block. The rigid framework is formed by mixing the stone fragments with dry cement powder and, as the fragments pass from the mixer to the mold, wetting the powder remaining in contact with them by a fine spray of H_2O . After the materials have set sufficiently to bear removal from the mold, the framework is immersed for some days in H_2O , to which has preferably been added Na_2SiO_3 .

Brit., 7,954, Mar. 30, 1914. SIR A. DENNY and D. G. ANDERSON. A composition for coating ships' decks, floors, etc., consists of a mixt. of gypsum cement and a relatively small proportion of portland cement, together with filling materials, such as pumice, coke breeze, asbestos, sawdust, etc., mixed with H_2O , or a dil. soln. of Na_2AlO_4 . The term "gypsum cement" does not include plaster of paris, stucco, or like hydrated sulfates. In an example, 100 parts of gypsum cement, 15 of portland cement, 20 of pumice, and 20 of sawdust are made into a stiff paste with a 2% soln. of Na_2AlO_4 , or with H_2O . Cf. C. A. 8, 3223.

Ger., 284,221, May 25, 1912. E. BOUVIER. Mfg. a hydraulic cement, of constant volume, by subjecting a pulverulent mixt. of lime and siliceous materials, such as clay, sand, acid slags, etc., to the action of superheated steam, and burning the product. The steamed mass is heated slowly up to 400–600°, until not only the moisture taken up in steaming, but also a portion of the combined H_2O (of hydration), is driven off, giving a product with about 9% H_2O of hydration. E. g., 3 parts of CaO and 1 part of clay, sand, acid slags, and the like, are intimately mixed as powder in the dry state. By the addition of some H_2O a pasty mass is formed, from which building blocks or other shaped masses are made, or the mass is placed in containers. The shaped or cased product is then subjected in an autoclave to the action of steam under a pressure of 8–12 atms. The period of steaming and the pressure depend upon the

comp. of the lime and siliceous admixts. The steamed product is then placed in a tunnel furnace, and heated there, slowly, up to 400–600°. The moisture taken up in the steaming process is first driven off, and then a portion of the hydrate H_2O . The temp. must not be allowed to exceed 600°, since otherwise all hydrate H_2O would be driven off and the product would be rendered inapplicable as a hydraulic cement. After removal of the product from the furnace it is ground fine, as cement. It sets and hardens under H_2O , without working.

Ger., 284,222, May 25, 1913. J. E. BAKHR. A furnace building material is obtained by first burning dolomite in alternate layers with coke in a shaft furnace, grinding the burned product, and again burning it in admixt. with combustion residues as sintering materials. E. g., the crude dolomite is crushed to pieces of 77–102 sq. mm. cross section, and then burned in the shaft furnace in alternate layers with coke. The burned dolomite, together with the fuel residues, is ground and sifted. This mixt. is burned in a revoluble tube furnace at about 1300°. The product can be used in the lining of metallurgical furnaces, for stopping tap holes, for the prepn. of furnace bottom, etc.

J. D. PENNOCK.

Effect of high ignition voltages on the accuracy of bomb calorimeter determinations. E. J. DITTRUS. *Met. Chem. Eng.* 13, 480–1 (1915).—In the detn. of calorific values with the bomb calorimeter it is necessary to ignite the weighed portion of the substance in an atm. of O, under pressure, by melting a small piece of Fe wire (approx. 0.01 g.) with an elec. current. A small calorific increment results, due to the passage of the current. It is contended that high voltages enhance this increment. In order to det. the value of this source of error several expts. were made. The data obtained lead to the conclusion that unless great accuracy is required the ignition voltage is not an important consideration. That is, in the detn. of the calorific value of coal, oil, etc., an error of 0.2% is permissible, and the ignition voltage need not be seriously regarded.

Gaseous combustion at high pressure. W. A. BONE, HAMILTON DAVIES, H. H. GRAY, H. H. HENSTOCK AND J. B. DAWSON. *Proc. Roy. Soc. London (A)* 91, 464–5 (1915).—Report of work in 1906–12 at Univ. Leeds. Expts. in which mixts. of CH_4 with less than its own vol. of O were exploded in steel bombs at initial pressures of 8 to 32 atm. have given results in harmony with the theory of "hydroxylation" of Bone, put forward some years ago. The influence of various secondary reactions upon the products of the primary oxidation while the gases are cooling down after attainment of max. pressure is discussed in the light of exptl. results. Expts. on an equimol. mixt. of C_2H_4 and O_2 also confirmed the hydroxylation theory. From expts. on the relative affinities of CH_4 , H_2 , and CO for O in flames it was shown (1) that the affinity of CH_4 is at least 20 times as great as that of H_2 , and (2) that when mixts. corresponding to $CH_4 + O_2 + xH_2$ are fired under high initial pressure, in which the partial pressures of CH_4 and O_2 are kept const., and only x varied, the distribution of O between CH_4

and H_2 varies as x^2 , a circumstance which means that H is burnt *directly* to steam in flames as the result of the trimolecular change $2H_2 + O_2 = 2H_2O$ and not indirectly through H_2O_2 . The affinity of CO is comparable to that of H_2 in flames. Mixtures corresponding to $C_2H_4 + O_2 + xH_2$ were exploded at high initial pressure, and it was found possible to increase x up to 8 without causing any deposition of C on explosion. In the final section, expts. are described in which the whole pressure curves, up to and far beyond the attainment of max. pressure, were recorded when mixts. corresponding to (1) $2H_2 + O_2 + 4N_2$, (2) $2CO + O_2 + 4N_2$, and (3) $CH_4 + O_2 + 4N_2$ are exploded under initial pressures of about 50 atm. The rates of attainment of max. pressure in each case have no direct relation to the order of affinities of the various gases for O .
E. B. MILLARD.

Furnace efficiency. F. B. DUNN. *J. Elec. Power & Gas* 34, 512; 35, 24(1915).—A general discussion of proper combustion, gas analysis control, and the heat of combustion in gas- and oil-fired furnaces.
W. E. RUDER.

Vertical retorts for average and small size gas works. J. HUDLER. *Feuerungs-technik* 3, 209-13(1915).—A new vertical retort adapted for use in small gas works is described and results obtained with it given. The radiation losses are decreased particularly through the shortening of the retort. The advantages claimed are that small works can have a large number of units in operation, resulting in a reduction of unit heating surface exposed to cooler surfaces, a better control of the variations of the supply and demand, a more uniform gas and a greater fluidity of the sepd. tar.

H. R. GUNDLACH.

Spent oxide. VAN OOSTRAM MEYERS. *J. Gas Lighting* 131, 189-91(1915).—Various expts. showed that Fe_2O_3 takes up H_2S as well as does $Fe_2(OH)_3$ and that slightly burning the oxide increases its absorbent power about 20%. Acids have no deleterious influence on the activity of purifying materials. An absorption much higher than the average was obtained with bog ore after it had been treated for 1 hr. with CO_2 .
B. W. GRIMES.

Removal of carbon disulfide from gas. TEUNE. *Hel. Gas* April, 1915; *J. Gas Lighting* 130, 334.—The expt. was made to det. the ability of "spent oxide" containing a large quantity of free S to absorb CS_2 . Although the S was in a fine state of division it had only a slight capacity to dissolve CS_2 . The absorptive capacity was so slight that no actual purification process could be based upon it.
C. A. COLE.

Determination of benzene in gas mixtures. G. A. BURRELL AND I. W. ROBERTSON. *J. Ind. Eng. Chem.* 7, 669-70(1915).—The detn. is made in an app. which includes a bulb containing P_2O_5 for absorbing H_2O vapor. After introducing the gas mixt. the app. is cooled to -78° by immersion in a mixt. of solid CO_2 and acetone or alc. At the end of 10 min. as much gas as possible is removed with the aid of a vacuum pump; in this way practically everything is removed except C_6H_6 . The app. is then allowed to assume ordinary temp., and the pressure of the C_6H_6 measured. This pressure compared to atm. pressure gives % C_6H_6 . The method can be used with illuminating gases, etc., but is not applicable in the presence of C_7H_8 .

ISADOR MILLER.

Causes of coloring of ammonium sulfate produced from ammoniacal liquors obtained in the distillation of coal. G. BIANCHETTI. *L'industria* 29, 190(1915); through *Ann. chim. applicata* 3, 376(1915).—The colorings depend upon the impurities of the H_2SO_4 used. A gray color may come from Cu and Pb sulfates, a blue or red color from the action of cyanogen compds. on the Fe compds. of the acid, and a yellow color from sulfide of As or Cd .
S. LEVY.

The Beckton toluene recovery plant. ANON. *J. Gas Lighting* 129, 798(1915).—By using a limited amt. of oil in the washers, a little C_6H_6 is extd., but a max. amt. of toluene is absorbed. From the washer the oil containing toluene, etc., is pumped through countercurrent heat economizers to the still where the wash oil is sepd. from the light oil by means of steam. The mixt. of light oil is rectified in a fractionating boiler. A yield of about $\frac{1}{3}$ gal. of pure toluene per ton of coal is obtained.

C. A. COLE.

The improved Jones oil gas process at the Potrero Gas Works, San Francisco. E. C. AND L. B. JONES. *Am. Gas Light J.* 103, 23-7(1915).—A new process is described for the prep. of oil gas of high calorific value and high CH_4 content, eliminating the production of lamp black. The formation of lamp black is prevented by dissociating the oil under pressure in an atm. of gas obtained from previous operations. The app. consists of 2 column-like steel shells, connected at the bottom with a throat piece, and filled with checker bricks. These bricks are heated by burning oil among them, and act as heat reservoirs, subsequently giving up the heat to decompose the oil during gas making. Uniformity of temp. is obtained by passing steam through the app. The gas obtained by the new process has an av. heating value of 600 B. t. u. per cu. ft., and contains 38.3% H and 48.9 CH_4 . The generating sets actually in use have a rated daily capacity of 5,000,000 cu. ft.

P. J. COLE.

Increasing the use of coke. C. VOLK. *Z. Ver. deut. Ing.* 59, 445-6(1915).—Coal with an addition of 10-20% coke may, in many cases, be burned economically on moving grates; on stationary grates the coke content may be increased, and in special cases the coke may be burned alone. It is possible to use a mixt. of 15-50% coke in bituminous coal-gas producers.

H. R. GUNDLACH.

Deterioration of fireclay goods in coke ovens and gas retorts. I. THOS. HOGATE. *Gas World* 63, 32-3(1915).—Previous discussions of this question, spoken of as corrosion, are in most cases stated in a fragmentary manner making it difficult to locate the causes of what are apparently contradictory experiences and opposed explanations. It is the aim of this article to endeavor to get as many of the facts as possible and see whether they can be reconciled or at least furnish a starting point for further observation upon a systematic basis. The effect of carbon deposits upon cracked bricks is referred to, also the possibility that even volatile iron combinations, e. g., iron carbonyl, may exert an influence on the quality of the bricks. There is a further discussion covering the effects of NaCl in the coal, NaCl in the water used for washing coals, of the corrosion when firebrick containing a high percentage of alumina is used and also the resistance of silica brick. II. *Ibid* 50-3.—This part takes up the discussion of the loss of Al, the SiO_2 - Al_2O_3 ratio before and after a supposed change, the accretions of Mn_2O_4 and of Na, K and Ca. The changes are shown by complete tables of analyses. An accession of chloride and well-known chemical activity of $AlCl_3$ leads one to inquire whether the last-named substance may not be an intermediary in the mischief by acting as a powerful catalyst. A further discussion takes up the role of iron carbonyl, the effect of Fe as a flux in relation to SiO_2 and Al_2O_3 content, the tendency of SiO_2 to change its vol., deposits of C due to imperfection in the heating arrangements, and the importance of the water used in coal washing and of elec. considerations.

M. L. TROWBRIDGE.

The coke-handling plant of the New York Consolidated Gas Co. ANON. *J. Gas Lighting* 130, 636-8(1915).—An illustrated description.

E. J. C.

U. S., 1,147,790, July 27. A. MCD. DUCKHAM. Vertical retort for making coal gas.

U. S., 1,148,011, July 27. G. L. DAVIES and W. E. WINDSOR-RICHARDS. **Separating constituents of coal tar.** The tar is acidified, *e. g.*, with about 3% H_2SO_4 , and then mixed with kerosene or other light petroleum oil or with an animal or vegetable oil (preferably 4% of light mineral oil) and allowed to stand to complete the sepn. of the lighter from the heavier constituents of the tar. Then the lighter constituents are drawn off or decanted and the residue is aerated and washed with hot H_2O to remove S and coloring matter.

U. S., 1,148,925, Aug. 3. C. PICARD. **Storing acetylene.** The container is coated on the inside with glue, sol. silicate soln. or other adhesive and fibrous material is then blown into the container to adhere to the coating and aid in supporting the porous filling so that it cannot subsequently settle out and leave cavities within the vessel in which explosions might occur.

U. S., 1,149,056, Aug. 3. W. O. HOUSTON. **Gas-producer for furnaces.**

Brit., 17,729, Aug. 3, 1913. H. PLAUSON. A liquid fuel is composed of a suspension or colloidal soln. of coal or charcoal in H_2O , benzene, petroleum, naphtha, naphtha residues, tar, or the like. H_2O is employed in fuels for heating purposes, and hydrocarbons in those for internal-combustion engines. In making the suspension, coal or wood charcoal or the like is disintegrated sufficiently to pass through a sieve having, say, 40,000 openings to the sq. in., and is then mixed with the desired liquid and ground at a high speed or for a long time. *E. g.*, coal and H_2O require to be ground between smooth disks, plates, or spherical surfaces under a pressure of 60-100 atms. for 15 mins. to 2 hrs., to produce an emulsion or colloidal soln. Small amts. of colloids may be added, such as soap, milk (casein), gelatin, albumin, or the like, when using H_2O , or soap soln., India rubber, or the like, when using hydrocarbons. Tannin may be employed. A suspension, fine enough for use as fuel, may be obtained by trituration with colloids under 10 atms. for 10-15 mins., and a colloidal soln. by longer grinding. According to the provisional specification, HCHO , permanganate, chromic acid, tungstic acid, or the like, anhydrides, etc., may be used to decompose the coal particles.

Brit., 21,327, Sept. 22, 1913. J. S. ATKINSON and COKE OVEN MACHINERY CO. and K. HUESSENER. In regenerative reversible furnaces for the manuf. of steel, glass, etc., burners are employed at each end of the furnace; to these both gas and primary air are supplied, combustion not taking place until the mixt. meets a secondary air supply.

F. M. ROGERS.

Petroleum as fuel under boilers and in furnaces for heating, melting, and heat treatment of metals. W. N. BEST. *Bull. Am. Inst. Mining Eng.* 1915, 1527-38.—A general review and discussion with numerous illustrations. F. W. SMITHER.

Determination of mineral oil in dégras and in mixtures with fatty substances. K. BIAZZO. *Ann. lab. chim. cent. delle Gabelle* 7, 349(1914); through *Ann. chim. applicata* 3, 374-5(1915).—To the aq. soln. of the products of saponification there is added phenol, which saturates the excess of alkali and renders the sepn. of the aq. and ethereal layers rapid and clear, when Et_2O is subsequently used for extn. The ethereal layer is then shaken with KOH, washed with H_2O , dehydrated and distilled. S. LEVY.

Demulsification values of mineral lubricating oils for use in steam turbines. ARNOLD PHILIP. *J. Soc. Chem. Ind.* 34, 697-701(1915).—P. has devised an app. for detg. the power of an oil to resist emulsification with water. 500 cc. of oil and 500 cc. of H_2O are agitated at 100° for 5 min. The mixing is accomplished by means of a mechanical stirrer driven by an elec. motor at the rate of 350-400 r. p. m. This speed gave the most concordant results. Agitation by blowing with air and by shaking were unsatisfactory. After mixing, the emulsion is run into a 1000 cc. graduate and allowed to stand 24 hrs. The vol. of clear oil on top is read and calcd. as percentage of the original 500 cc. This percentage P. calls the demulsification value. 98% is the highest value obtainable due to mechanical losses. From the examn. of over 700 samples P. finds that an oil having a demulsification value of 90% or over will give no trouble with emulsions in use on steam turbines. Tables are given showing the effect of adding 1% of fuel oil high in bituminous matter to oils of high demulsification value. In every case the demulsification value is lowered. P. is not sure whether this is due to the bituminous or to the nitrogenous matter or S compds. in the fuel oil. P. considers the test of great value in detg. whether an oil will emulsify in use.

F. M. ROGERS.

Specific gravity of the cold and the hot fractions of the solid paraffins of naphtha. M. A. RAKUZIN AND A. A. ARSEN'EV, *J. Russ. Phys. Chem. Soc.* 47, 642-5(1915).—Detns. of the sp. gr. of the different fractions of paraffins obtained from a sample of naphtha previously examd. (C. A. 9, 2148) showed that its middle fractions are lighter than itself. This accounts for the impossibility of removing them by centrifugaliza-

tion. Scheller's statement that the yield of paraffins from naphtha differs with the method of distn. (C. A. 7, 3832) needs verification.

H. M. GORDIN.

Preliminary experiments on the effect of temperature control on the yield of products in the destructive distillation of hardwood. R. C. PALMER. *J. Ind. Eng. Chem.* 7, 663-9(1915).—Lab. distns. on 70-lb. samples of maple, beech and birch. The effect of controlling the distn. (lowering the temp. of reaction and decreasing the speed of distn. at the critical stage) is to increase the yield of alc. 45% for maple, 6% for beech, and 7% for birch, while increase in AcOH was 2, 9 and 5%, resp. The lab. distns. gave 40% more acetate of lime than usual com. yields. The practical value of these results was detd. by a study of the controlled distn. in a com. retort, the raw material averaging 93% maple, 4% birch and 3% beech.

ISADOR MILLER.

The destructive distillation of Pacific coast kelps. D. R. HOAGLAND. *J. Ind. Eng. Chem.* 7, 673-4(1915).—Distn. of 1 kg. samples of kelp (*Macrocystis pyrifera*), oak and Douglas fir was effected in an Fe retort of 1.5 gal. capacity. The yield of AcOH from kelp was only 0.2 that from the fir and 0.1 that from the oak, the alc. yields standing in the same proportion. Tar oils to the amt. of 4-7% by wt. dry kelp were recovered and this oil had d_{17} 0.984; on fractionation it yielded 11% between 0 and 125°, 27% between 125 and 250°, 23% between 250 and 300° and gave 39% tar residue. Most of the K_2CO_3 can be recovered as a high grade product by leaching the charcoal.

ISADOR MILLER.

Production of (wood) pitch and tar in Russia. H. D. BAKER. *Commerce Reports* 191, 803(1915).

Improved Jones oil-gas process (JONES) 21. Oil-burning metallurgical furnaces 9. Substitutes for petroleum, etc. (GARLEPP) 18. Composition of the solid fraction of the naphtha paraffins as criterion of geologic age (RAKUZIN) 8. Petroleum in eastern Mexico (DUMBLE) 8. Formation of natural naphtha (CHICHIBABIN) 8.

U. S., 1,148,763, Aug. 3. J. G. FAGAN. Extinguishing oil fires by blowing onto the surface of the burning oil a light powder such as sawdust or cork (or other material which will float on the oil), the particles of which are coated and mixed with a fire-extinguishing liquid, such as reaction products of $NaHCO_3$ and H_2SO_4 .

U. S., 1,148,834, Aug. 3. F. F. EMORY. Oil filter.

U. S., 1,148,990, Aug. 3. M. C. ROGERS. Oil filter.

U. S., 1,149,027, Aug. 3. J. H. CASTONA. Distilling resinous wood. The wood is subjected to the direct action of superheated steam without pressure to drive out the turpentine without distg. the pine oils from the wood. Then the wood is treated with satd. steam while heating the bottom of the still from the exterior to retard condensation and evap. the condensate. The vapors thus produced are condensed and the turpentine is sepd. from the H_2O of the condensate. The pine oils are then distd. from the wood with superheated steam and the resin is dissolved from the wood by leaching with a solvent, the residue of which is recovered by steam distn. Cf. C. A. 8, 3628.

Brit., 20,188, Sept. 3, 1913. R. HENSE. Volatile hydrocarbons suitable for use as fuel for internal-combustion engines are obtained from a mixt. of heavy hydrocarbons with light hydrocarbons or alc. by adding to the mixt. a resinous substance and an oxidizing agent, distg. the mixt., and treating the distillate with O_2 . In some cases the distillates obtained above 250° are mixed with turpentine, resin, or amyl acetate, or with some of the distillate obtained at a lower temp. before the treatment

with ozone. If the hydrocarbons have already been distd., further distn. is omitted. The liquid mixt. is freed from H_2O either by freezing or by means of anhydrous Na_2SO_4 or other salts. Crude naphtha, mineral oils, tar products, and benzene and resin products may be treated by this process. In an example, crude naphtha, mixed with a small quantity of benzene, is treated with $NaOH$, and a soln. of resin or turpentine in benzene, benzine, or petroleum is added. A soln. of picric acid or Mg or other peroxide is then added, the mixt. is acidified with H_2SO_4 and is allowed to stand and settle. The oil is then sepd. from the lye, dehydrated with anhydrous Na_2SO_4 or by freezing with cold air, if necessary, and is then distd., the distillate being purified and enriched with O_3 and any ppt. allowed to settle out. The products are used as motor fuels, or for vapor lamps, or in dry-cleaning. The products collected above 250° may be used as turpentine substitutes or for extg. grease from bones, and the distillate and the residue may be employed for making boot blacking and boot creams. In an example of the use of an already distd. petroleum, the refined oil is mixed with benzine and C_6H_6 , the resin, turpentine, or amyl acetate is added, and the product is ozonized.

Brit., 7,700, Mar. 26, 1914. TRIESTER MINERALÖL-RAFFINERIE. App. for separating solid paraffin from oil, or hard paraffin from soft paraffin.

Brit., 20,488, Sept. 10, 1914. BADISCHE. Hydrocarbons, chiefly such as are easily liquefiable, and oxygen derivatives of hydrocarbons are obtained by passing CO and H_2 , mixed or not with other gases, in the proportions of at least $\frac{1}{2}$ of a vol. of the former to 1 vol. of the latter, over a heated catalyst under a high pressure exceeding that of 5 atms. In examples, the prepn. of hydrocarbons boiling from 20° up to 250° , of olefins, paraffins, and benzene hydrocarbons, of alcs., ketones, such as acetone, aldehydes such as $HCHO$, acids such as $HOAc$ and its homologs, and other products is described. In some cases, a basic compd. is added to the catalyst, and mixts. of 2 or more catalysts may be employed.

23. CELLULOSE AND PAPER.

A. D. LITTLE.

Advances in the chemistry of cellulose (1913-1914). E. HEUER. *Kunststoffe* 5, 126-7, 138-40, 149-51 (1915); see *C. A.* 9, 1690. F. W. SMITHER.

Differentiation of parchment paper from pergamin paper. G. ANNONI AND G. RODANO. *Ann. lab. chim. Gabelle* 7, 19; *Ind. chim. min. met.* 2, 129(1915).—Since parchment paper consists of an SO_3H deriv. of cellulose transformed by H_2O into hydrocellulose which with I gives a blue color, when the paper is treated with a reagent containing I (like $ZnCl_2$), there is instantly formed a violet spot which gradually darkens and when placed under running H_2O turns to an intense azure which persists for a long time. Under the same conditions, the reagent dropped upon pergamin paper likewise turns violet, though more slowly, but under running H_2O all color disappears or only a very faint violet stain remains. Moreover, pergamin paper gives the Moransky test for resin (red-violet color with Ac_2O followed by H_2SO_4), while parchment paper does not. CHAS. A. ROUITLER.

U. S., 1,145,498, July 6. J. L. MERRILL. Paper-pulp from ligneous materials such as flax straw, flax-tow and similar substances, is obtained by treating the material with about 15-25% its wt. of milk of lime, steaming under 75-100 lbs. pressure per sq. in., cutting into small pieces and washing.

U. S., 1,147,996, July 27. H. WREDE. Smooth coated paper for fine printing work. See Brit., 4,706 (C. A. 8, 2804).

Brit., 16,940, July 23, 1913. W. PLINATUS. Solid or liquid solutions of cellulose esters, such as nitrocellulose and organic acid esters, are prep'd. with the aid of aliphatic or aromatic esters of polyhydric alcs., such as the butyrins, the acetins, the esters of benzoic acid and glycerol, and the esters of glycol. Substances such as camphor, waxes, resins, oils, caoutchouc, and tar products may be dissolved in the solns., and the products obtained used in the manuf. of plastic masses, paints, impregnating compds., and artificial threads. Other solvents may be added. Solid solns. can be prep'd. from nitrocellulose without the aid of camphor by the use of these esters, and in the prepn. of these solns., it is sufficient to mix the substances between the heated rollers of a kneading-mill. When camphor is to be added, this may be dissolved in the ester of a polyhydric alc. before mixing with the nitrocellulose, or the nitrocellulose may be mixed with the solvent ester, pulverized camphor added, and the whole again kneaded. When these esters are used as solvents, resins may be employed as gelatinizing media in the place of camphor, and the resins may be worked up with the nitrocellulose by any of the methods above referred to. Filling substances, such as paper, fibers, dyestuffs, and salts, may be added.

Brit., 6,227, Mar. 11, 1914. FARBW. v. M. L. & B. In mfg. fancy papers, paper rendered rugged and uneven on the wirecloth by methods such as are described in 10,529, 1908, and 15,555, 1909, is flooded with a dil. dye soln., such as the waste H_2O dripping through the wirecloth and still containing coloring matter or colored particles. Dye solns. or differently colored fibers or particles of mica or pigments may be added to the waste H_2O . The colored H_2O fills up the depressions in the web and colors them a deeper shade than the elevated parts.

Brit., 6,677, Mar. 17, 1914. H. ARLEDTER. Treating or bleaching cellulose and other similar fibrous materials, either in the pulpy, spun, or woven condition, by a modification of the app. and process described in 16,085, 1912 (C. A. 8, 247). An elec. sparking device is employed in connection with a system of pipes and one or more pumps by which gases are withdrawn from the top of the treating vessel and returned, with fresh air and Cl, to the bottom. A continuous current of ozonized air and Cl is thus passed through the vessel by vacuum and pressure exerted in the opposite direction to that in which the liquid and solid materials traverse the vessel. Hypochlorite, or HCl, $H_2C_2O_4$, CO_2 , SO_2 or HNO_2 , may also be added during the operation. The sparking tube may be at the suction or delivery end of the air-pump, or between 2 pumps; or it may be inside, under the dome of the treating vessel. In some cases, the circulation and mixing of the material and liquid by means of the pump and disintegrator described in the principal patent will be unnecessary, the agitation and mixing produced by air current being sufficient. The specification mentions the treatment of wood pulp, jute fibers, straw, wool, and hair, and states also that linen and other cloth and spun yarn may be bleached by hanging or laying them up in the vessel and pumping the liquor through them, while circulating the ozonized air in the opposite direction. A battery of vessels may be used, the gases from one being passed to the next. The gases may be cooled before delivery to the bottom of the vessel.

Brit., 6,874, Mar. 18, 1914. T. H. NASH. App. for boiling and washing rags and the like used in the manuf. of paper.

Ger., 274,550, May 20, 1914. VEREINIGTE GLANZSTOFF-FABRIKEN A.-G. Mfg. threads, films, or plates. See Fr., 454,011 (C. A. 8, 257).

Ger., 282,592, Oct. 19, 1913. AFLENZER GRAFIT- UND TALKSTEINGEWERKSCHAFT, G. M. B. H. In a process of tinting paper, pulp, textiles, and the like, in gray or black, graphite powder is incorporated. Graphite powder is soft, tints uniformly, and has a strong covering power; it also imparts to the paper flexibility and a smooth texture. The calendering process requires less power when the paper is so treated, and the appearance of the product is better. Preferably the graphite is added to the material before the latter is sized. If graphite powder and aniline colors are used conjointly, the fastness of the resulting colors to light is claimed to be increased.

Ger., 283,006, Feb. 26, 1913. ANTOINE REGNOUF DE VAINS and J. F. T. PETERSON. Removing ketones from lignocelluloses preliminary to bleaching by treating with chloride of lime soln. and washing out the resulting chloroketone. The removal of the chloroketone is aided by rendering the wash H_2O alk.

Ger., 283,111, Dec. 9, 1913. E. HEUSER and G. BORDEKER. Mfg. resin size from unsaponifiable caoutchouc resins and colophonium or other saponifiable resins. Previous attempts to use the cheap caoutchouc resin together with the more expensive colophonium in the manuf. of resin size for paper were unsuccessful inasmuch as the colophonium was rendered unsaponifiable by reason of the presence of the caoutchouc resin. In the present process colophonium and unsaponifiable caoutchouc resin are mixed mechanically in a finely pulverized state. Upon boiling up this mixt. in an aq. soln. of caustic or carbonate (of an alkali metal), a resin size is obtained which forms a white emulsion with cold H_2O such as is necessary for sizing paper stock. The saponifying agent (soda) may be added, in powder form, to the mechanical mixt. of colophonium and caoutchouc resin, whereby a pulverulent prepn. is obtained which need only be boiled up in H_2O to prepare the resin size. The caoutchouc resin does not saponify in this process; it is simply emulsified in the resin soap.

Ger., 283,199, July 11, 1914. Addition to 259,691 (C. A. 7, 3227). B. JIROTKA. In the manuf. of articles from cellulose or lignose, the principal process is modified in that the articles, before complete drying, are coated with a quick hardening substance, such as gypsum or the like, or imbedded in it. In order to prevent adhesion of the gypsum, the article is covered previously with a neutral layer such as fat or shellac.

Ger., 283,286, Apr. 16, 1913. Addition to 274,550 (*supra*). VEREINIGTE GLANZSTOFF-FABRIKEN A.-G. In the manuf. of threads, films, or plates from viscose, tartaric and citric acids, and like hydroxy acids which form readily sol. Na salts, all of which are relatively cheap and easily regenerated, can be used instead of lactic and glycolic acids as specified in the principal patent. E. g., 300 g. Na citrate, 300 g. citric acid, and 1000 g. H_2O , are heated to 50° . A matured crude viscose soln., which has been heated for about 100 hrs. at 15° , is squirted into the pptg. bath and wound for transportation to the centrifuges. The threads, at first clear and sol. in H_2O , become whitish. The complete decomp. is completed readily by passage through a second bath prepared from the first bath by a 5 times diln. with H_2O . The product is then washed with H_2O , dried under tension, then desulfurized and bleached.

Ger., 283,371, Mar. 8, 1914. Addition to 268,243 (C. A. 8, 1669). FARBW. v. M. L. & B. Mfg. paper with designs on both sides, according to the principal process in which H_2O -sol. fat solvents, such as alc., HOAc, HCOOH, and the like, are applied

by means of rolls to one side of the paper, and the color soln. is applied thereon. The design is stronger and sharper when solns. of hygroscopic substances, such as $MgCl_2$, are added to the solvents.

Ger., 283,506, Nov. 14, 1913. M. SCHMIDT. Removing the salty taste of parchment paper treated with $NaCl$ soln., by adding to every liter of the $NaCl$ soln. with which the paper is to be treated, a soln. of 0.25–3 g. saccharin in H_2O . The parchment paper is immersed in this soln., and then dried on drying cylinders.

Ger., 283,736, Nov. 29, 1913. P. C. SCHAANNING. Construction and operation of an app. for dehydrating wood fiber in cellulose plants.

Ger., 283,751, Apr. 15, 1914. E. ALTMANN. Sizing paper by adding an emulsion of gelatin and talc to the paper stock. On contact with H_2O talcum forms colloidal substances, such as the hydroxides of Si and Mg . These take up colors and form about them a colloidal coating which protects the color. The talc, besides taking up the color, absorbs dextrin, albumin, gelatin, and other colloidal substances. This sizing is similar to resin sizing, even superior in some respects. To 1 liter emulsion, 5 g. white gelatin and 10 g. finely ground talc, taken up in hot H_2O at $70-75^\circ$, are used.

Ger., 283,752, Mar. 15, 1914. M. LÜTTICH. Mfg. a paper for documents, tickets, and the like, by applying, continuously or intermittently, to the paper band before it passes through the drier, a line of color, which in the finished paper does not appear sharply defined, but as a wash color.

Ger., 283,931, Sept. 10, 1911. ERBEN DES VERSTORBENEN DR. E. TRAINER. Process of utilizing sulfite cellulose back waters for tech. and agricultural purposes. The high content of SO_2 or of compds. splitting off SO_2 readily, and of lime, and the almost entire absence of albuminous substances, have been prime factors in rendering these back waters inapplicable as fertilizers and fodder. The sulfite liquors make a good medium for oxidizing microorganisms, by the action of which the S compds. specified are oxidized to less injurious compds. The organisms *B. subtil.*, *B. vulgaris*, *B. acet.*, *B. mycoid.*, *B. pasteur.*, *B. acid lact.* are suitable for this purpose. Irrespective of the oxidation of the S compds., whereby a considerable portion of the lime is combined with the H_2SO_4 formed as $CaSO_4$, the lyes are enriched by the organisms themselves in useful organic compds. The organism selected, or a number of them, are cultured on the soil containing the lyes, in pure culture, and then the principal portion of the lye is inoculated with this pure culture. The conversion of the lye is favored by the passage of air, so that the inoculated lye is allowed to trickle over step-work, or the like, and heated to a definite temp. In order to facilitate the action of the microorganisms, a portion of the S compds. may be removed from the crude lye before the inoculation. The reaction is adjusted, also, before inoculation. In order to incorporate albuminous matter, the liquors, freed as much as possible from S compds., are fermented with yeast, and the mass is then dehydrated until fit for use as fodder or fertilizer. The wood waste resulting from cellulose manuf. can be rendered fermentable by suitable treatment, and added to the liquors before fermentation. Also, fermentable waste matter of the sugar and starch industry can be used.

24. EXPLOSIVES AND EXPLOSIONS.

C. E. MUNROE.

Tolerances in tests of permissible explosives. *J. Ind. Eng. Chem.* 7, 716–7(1915).—Having admitted some 150 explosives to the Permissible List because, as submitted by the manufacturers, they had passed all of the required tests, the Bureau of Mines

officials deemed it essential, in order that all of the requirements of a Permissible Explosive shall be met, to secure tolerances for retesting samples of these various explosives as they are offered in commerce or used in the mines. It was recognized that identical results could not be obtained in the tests of the original and the "field" samples and, therefore, a committee was appointed to ascertain what tolerance should be officially adopted in the case of each chem. and physical test required. This committee, after analysis and study of all the data accumulated at the Station since its foundation, made a report. The manufacturers of the United States were then invited to meet in conference with the Bureau's officials to discuss this report. This was done on June 7th last and the tolerances fixed upon, which are set forth in detail in this journal, are now confirmed by the Bureau.

CHARLES E. MUNROE.

High explosives. GEORGE W. MACDONALD. *Nature* 95, 508-9(1915).—A popular article giving historical statistics and the various names, under which the same explosive is known in various countries.

CHARLES E. MUNROE.

Blasting explosives in northern Argentina. *Commerce Repts.* 174, 452(1915).—Notes, nature and extent of uses, kinds and quantities of explosives, together with sources of origin and methods of packing.

CHARLES E. MUNROE.

Mines, shells and high explosives. VIVIAN B. LEWES. *Engineering* 100, 65-6 (1915).—Résumé of a popular lecture at Royal Society of Arts giving an account of the explosives being used in the present war with some statistical and historical data relating to them. L.'s composition for ammonal differs from that usually given and he says "aniline could be converted into a further compd., which would yield the greatest explosive hitherto made."

CHARLES E. MUNROE.

Explosion in mixing house of factory of Nobel's Explosives Co., Ltd., at Ardeer. H. CONINGHAM. *Home Office Rept.* 213, 6 pp.(1915).—The explosion occurred in the operation of charging and stirring thin nitroglycerin-nitro-cotton jelly in a brass mixing pan provided with vertical bronze stirrers preparatory to mixing it with the material necessary for making it into "Gelignite" or "Samsonite." The operation of charging was performed by placing the rubber-lined box, in which the jelly was stored and transported, on a stool beside the mixer, joining the edges of the box and the mixer with a thin sheet-lead saddle to prevent any explosive falling between the box and the mixing pan, and then taking the explosive across this saddle by hand. It is believed the explosion was due to this saddle, or a brass screw, having accidentally fallen into the mixing pan and become entangled between the blades of the paddles and the walls of the pan, developing sufficient friction to fire the explosive.

CHARLES E. MUNROE.

Explosion of nitro-cotton. H. CONINGHAM. *Home Office Rept.* 214, 6 pp.(1915).—Some 68 pounds of dry nitro-cotton were taken in galvanized iron bins into an incorporating mill authorized for treatment of wet nitro-cotton only. It is believed that the explosion was caused by friction in the removal of a lid on one of these bins or by dropping a lid on to an open bin containing dry nitro-cotton. There were over 2 tons of wet nitro-cotton in the building but none of it was exploded or even burned by the fire which succeeded the explosion.

Brit., 7,647, Mar. 26, 1914. A. C. PEARCY and CURTIS's & HARVEY. In mfg. explosives, adding a mixt. of KCl or NaCl, borax and KNO_3 to nitroglycerin-nitrocellulose explosives to render them safe against fire-damp, carbonaceous matter (except collodion cotton) being as far as possible excluded. One example contains 42.5 parts of nitroglycerin, 2.5 parts of collodion cotton, 20 of KNO_3 , 20 of borax, and 15 of NaCl.

Brit., 24,702, May 29, 1914. W. MACNAB and B. J. FLÜRSCHHEIM. Mfg. propellant explosives by mixing (1) one or more neutral polynitro compds. containing at least 4 nitro groups, such as $(NO_2)_4C_6H_4NH_2$ and $(NO_2)_4CMeNH_2$ with (2) 1 or more non-explosive organic colloids such as agar-agar, gelatin, and India rubber, and (3) an organic or inorganic nitrate or similar substance such as nitroguanidine and nitrates of urea, guanidine and Ba. Either (2) or (3) may be omitted. One example contains 68 parts $(NO_2)_4CMeNH_2$ ("tetryl"), 30 parts urea nitrate, and 2 parts of India rubber.

Ger., 281,510, Nov. 1, 1912. A. REBITZKI. In a fire-damp detector for miners' lamps, the heat produced by the aura surrounding an elec. heated incandescent body is used to det. the presence and the % content of the combustible gases.

Ger., 282,736, Sept. 20, 1913. R. HÖING and F. SCHWARZE. App. for preventing mine explosions by means of explosions which are produced immediately upon the opening of a water-spraying system.

25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

Indigotin content of some Japanese indigoes. S. SATO. *J. Ind. Eng. Chem.* 7, 675-6(1915).—Analytical data on 9 samples. The method employed was that of Berghthiel and Briggs (*J. Soc. Chem. Ind.* 25, 734(1906)). The samples were found to be low in indigo and high in ash.
ISADOR MILLER.

Tree dyes of the United States. ANON. *Hardwood Record* May 25, 1915; *J. Am. Leather Chem. Assoc.* 10, 434-6.—If the dye famine caused by the war makes it necessary, America can obtain many natural dyes from her own trees. Of these the yellow oak (*Quercus velutina*) is most important. A list of 11 other trees is given with a description of the dyes that can be obtained from them.
E. H.

The dyeing value of some indigenous dyestuffs. J. P. SRIVASTAVA. *J. Soc. Dyers, Colourists* 31, 122-5(1915).—The red and yellow natural coloring matters used in Europe are of American origin, and no systematic investigation seems to have been made so far to find similar dye woods in India. This is an account of an investigation of the dyeing values of certain coloring matters still used by native Indian dyers, conducted by order of the Director of Industries of India. In dyeing wool 5 methods were employed: (a) direct, (b) with 4% AcOH, (c) same as (b) but with after-treatment with $K_2Cr_2O_7$, (d) mordanting with $K_2Cr_2O_7$, (e) mordanting with $Al_2(SO_4)_3$. In dyeing cotton the following baths were employed: (a) tartar emetic, (b) $SnCl_4$, (c) alum, (d) $FeSO_4$. The following coloring matters were tried out: (1) "Harsinghar" (*Nyctanthes arbor-tristis*), of which the yellow flower gave a good yellow on wool, fast to milling with soap and soda. (2) "Tun" (*Cedrela toona*); flowers of this tree give a dye which colors wool with mordant (not fast). (3) "Tesu" or "Dhak" (*Butea frondosa*); this dyes wool shades fairly fast to milling. (4) "Hadli" or "Turmeric" (*Curcuma longa*); yellow dye of commerce. (5) "Arusa" (*Adhotoda vacica*); yellow dye whose fastness

in mordanted wool is fair. (6) "Jangli Nil" or "Wild Indigo" (*Tephrosia purpurea*); dyes wool mostly brown shades possessing very good fastness to milling. (7) "Safflower" or "Kusum" (*Carthamus tinctorius*); yellow color; dyes wool direct; not considered very useful. (8) "Naspal" or "Pomegranite Rind." (*Punica granatum*); gives shades varying from yellow to brown. (9) "Majith" (*Rubia cordifolia*); roots and twigs contain a dye identical with madder. (10) "Cutch" or "Katha" (*Acacia catechu*); commercial article; Catechu Brown on cotton one of fastest colors known. (11) "Patang" or "Sappan wood" (*Caesalpinia sappan*); this is a variety of Brazil wood and can be used on cotton for reds; suitable for calico printing. (12) "Lac dye;" commercial article of animal origin, giving brilliant scarlet shades on wool with tin mordant. (13) Indigo.

L. A. OLNEY.

New coloring matters on cotton. G. G. HEPBURN. *J. Soc. Dyers, Colourists* 31, 119-20(1915).—Many amines of the diphenyl series in a fine state of distribution, such as is attained in calico printing develop color when submitted to the action of alk. hypochlorite soln. Dianisidine hydrochloride printed upon cotton cloth with tragacanth thickening, dried and passed for 15 to 30 sec. through NaClO soln., containing 3 g. active O per liter, then washed and soaped, gave a heavy yellowish to reddish brown shade. This reaction was found to be pretty general although negative results were obtained with primary amines of the benzene series. *p*-Phenylenediamine gave deep brown shades. Auramine O conc., Night Blue, Methyl Violet 1B, Rhodamine 6G Extra, New Methylene Blue N, Methylene Violet 3RA, Azine Green, all give positive results when printed with AcOH and tragacanth. All the bases giving positive results contained either primary or secondary amino groups, but those containing neither gave no development of color. Upon replacing NaClO with Na₂O₂, no development of color takes place.

L. A. OLNEY.

A method of developing a fast chrome brown on wool. M. FORT. *J. Soc. Dyers, Colourists* 31, 147-8(1915).—The scientific basis of the new method lies in the diazotization of wool, its coupling with gallic acid and fixation of the dyestuff thus formed by means of K₂Cr₂O₇. Tannic acid may be substituted but it gives shades inferior in depth and adds risk of making the wool harsh. *Process*: First mordant the wool (with 3% K₂Cr₂O₇ and 2 1/2% tartar). Dye in bath made up with 3% gallic acid, 4% NaNO₂, 5% MeCOOH. Enter cold, bring slowly to boil, and boil 1 hr. Wooden dye baths are best. Its fastness is very good to all usual agencies, and it is unimpaired by heavy milling.

L. A. OLNEY.

Fastness of basic dyes to rubbing. M. FORT. *J. Soc. Dyers, Colourists* 31, 148 (1915).—The similarity between Leech's method of improving the fastness to rubbing of basic dyes on cotton (cf. Eng. Pat. 29,479, 1913; C. A. 9, 1694) and expts. of Fort are noted. In Leech's method, after tannin mordanting, the cotton is treated with Na silicate neutralized with HCl. In F.'s expts. H₃PO₄ and Al and Mg salts are used. Sn tannates gave the poorest and Al tannates the best fastness to rubbing. Fixing with large amts. of Al acetate gave the best results.

L. A. OLNEY.

Fixing vat-dyes by steaming. G. TAGLIANI. *Färber-Ztg.* 26, 73-5(1915).—Bleached and thoroughly washed fabrics are passed through a maltodextrin soln. (100 parts potato starch, 5 parts "diamalt" or equivalent malt ext. and 2000 parts H₂O), and are then dried as usual. The usual vat-dye printing is done, and the goods are then steamed in a small Mather-Platt. Colors are improved in brightness and intensity. It is advantageous to allow the printed goods to be exposed to the air for some time after steaming. Washing is done in a weakly acid bath containing a little Na₂Cr₂O₇. In case aniline black and certain other colors are printed, the process is not desirable. The best results are obtained with indigoids and sulfur dyes.

W. F. FARAGHER.

Practical results with nitrate discharges. M. FREIBERGER. *Färber-Ztg.* 26, 41-6, 57-60, 77-81(1915); cf. *C. A.* 7, 705. W. F. FARAGHER.

British solution of the dyestuff problem. *Reports of U. S. Dept. of Commerce; Chem. Eng.* 22, 3-6(1915).—An account is given of the organization of the company "British Dyes, Ltd.," on lines suggested in the announcement abstracted in *C. A.* 9, 1548. L. W. RIGGS.

Manufacture of Turkey red oils from free fatty acids. F. ERBAN. *Seifenfabr.* 35, 519-21(1915).—A 5% soln. was prep'd. and its behavior toward well, lime and gypsum H_2O , also toward $MgSO_4$, $AcOH$ and dil. H_2SO_4 noted. The tinctorial properties of the Turkey red oils for particular purposes are discussed. Cf. *C. A.* 9, 1400. E. SCHERUBEL.

Substitution of free fatty acids for neutral fats and oils in the textile industry. F. ERBAN. *Seifenfabr.* 35, 557-8(1915).—Good emulsions are obtainable from elain and mineral oil by neutralization of the elain with NH_4OH . In the jute industry mixts. of fish oil and mineral oil are used. In the yarn industry it has been found that soap solns. answer the purpose as well as neutral oils. In the printing of textiles fatty acids are not satisfactory as thickeners because they are not inactive toward colors. E. S.

Heat of hydration of some textile fibers. G. TESTONI. *Industria tessile e tintoria* 16, 23(1915); through *Ann. chim. applicata* 3, 378(1915).—The fibers, oven-dried and cooled in desiccators, showed a rise in temp. due to absorption of H_2O when exposed to moist air. This rise is almost const. for each kind of fiber, but varies from fiber to fiber. In flax and hemp it varies according to the degree of maceration and becomes equal to that of cotton when the flax and hemp fibers are treated so as to give cellulose. The phenomena were better studied by immersing a given wt. of dried fiber in a given vol. of distd. H_2O , and calcg. the increase of temp. on 100 g. dried substance. In the case of fibers like cotton and wool that give sufficiently great differences in temp. rise this property may be used to det. with good approximation the proportion of the said fibers in mixed threads. S. LEVY.

Reactions of silks made from cellulose. L. J. MATOS. *Chem. Eng.* 22, 41-2 (1915); see *C. A.* 8, 2810. L. W. RIGGS.

Measuring the impermeability of cloth and military fabrics. G. A. LEROY. *Compt. rend.* 160, 803-5(1915).—The app. consists of a glass cylinder 10-15 cm. high and 10 cm. interior diam., open at each end and the height graduated in cm. A brass collar is cemented to the inside of the lower end of the cylinder, the collar also forming a flange ring which is secured to a brass ring below by means of bolts. The fabric to be tested is cut into disks 12 cm. in diam. and clamped between the flange and ring, thus forming a cloth bottom to the cylinder. A tripod support, with an insulated portion in its column, carries a rigid disk of gilded brass 10 cm. in diam. A circular sheet of thin filter paper 12 cm. in diam., which has been previously dipped in an aq. soln. of K_2SO_4 and dried, is placed on the brass disk and the projecting ring 1 cm. wide is coated with paraffin or varnish. On the filter paper is placed a very thin circular disk of Pt or gilded Cu gauze 10 cm. in diam. and connected through a source of direct elec. current (110 volts) with the rigid brass disk. The cylinder with its cloth bottom is now placed on the support carrying the sheet of filter paper and thin metal gauze, and the permeability of the cloth to water shown by the passage of the current. The current is established when sufficient water passes through the cloth to dissolve the K_2SO_4 in the disk of filter paper, and this may be conveniently shown by introducing elec. lamps into the circuit. Cloth may be tested by filling the cylinder to various heights with water; or by a suitable arrangement of a sprinkling app. the permeability to artificial rain may be detd. In case of fabrics permeable to air, there should be a space

of 0.5 cm. between the cloth to be tested and the metallic gauze, while fabrics such as rubber goods impermeable to air should be in immediate contact with the gauze.

Emulsification and detergent action (SHORTER) 27. Leuco derivatives of indigo dyes (CHILIKIN) 10.

U. S., 1,147,778, July 27. W. BAUER and A. HERRE. Red indigoid vat dyes of the formula

obtained by reaction of dichloroisatin- α -anilide with 3-Ph-1-indanone and Ac_2O ; brownish red cryst., sol. in conc. H_2SO_4 with a blue color and forming a yellow vat with hydrosulfite which dyes cotton fast rhodamine-red.

U. S., 1,147,803, July 27. H. JORDAN and W. NEELMEIER. Dye obtained by combining the diazo compd. of di-*p*-aminobenzoyl-*p*-aminophenylureadisulfonic acid 64 with 1,*m*-aminophenyl-3-methyl-5-pyrazolone 37.8 parts; a yellow powder which dyes cotton bright greenish yellow which is rendered fast by treatment with CH_3O . By diazotizing the dye on the fiber an orange shade is obtained by development with β -naphthol and a yellow shade by development with 1-phenyl-3-methyl-5-pyrazolone.

U. S., 1,148,695, Aug. 3. J. G. KING. Warp-dyeing apparatus.

U. S., 1,148,698, Aug. 3. B. LOOMIS. Retting flax, hemp or similar fiber stock. The material is crushed and the juice is pressed out. Tannic acid is extd. with warm H_2O and the extd. juice and an aq. hard-wood ext. are circulated through the fibrous material and through a heater to ext. gummy and resinous substances. The latter are floated off and the liquor from which they are sepd. is reheated and continued in use until retting and degumming are complete. Then the liquor is drawn off and the fiber is dried by treatment with warm gas. Cf. C. A. 8, 420.

U. S., 1,148,966, Aug. 3. J. C. HERDEN. Vat dyeing. The material is treated with an alk. bath of leuco compd. of algol yellow 3G and alizarin indigo G or other leuco compd., the alkalinity of which is progressively decreased to lessen the solvent capacity of the bath and fix the dye on the fiber, and the latter is then oxidized.

Brit., 20,664, Sept. 12, 1913. BADISCHE. A highly reactive alkaline reagent is obtained by mixing caustic alkali, preferably KOH, with EtOH or MeOH in quantity not materially exceeding half a mol. proportion, while avoiding, as much as possible, pressure or admission of air. The product is suitable for use in place of molten caustic alkali in effecting reactions with anthracene derivs. These reactions can be effected by mixing the anthracene compd. with the above described product, and then exposing the mixt. to air; or the anthracene compd. may be first mixed with caustic alkali, and then with alc. while excluding air, and the mixt. then exposed to air; or a mixt. of anthracene compd. and caustic alkali may be treated in the presence of air with the requisite quantity of alc. in spray or vapor form. The reactions can be effected with or without external heating. According to examples, alizarin, indanthrene, and pyranthrene are obtained by mixing Na anthraquinone-2-sulfonate, 2-aminoanthraquinone,

and 2,2'-dimethyl-1,1'-dianthraquinonyl, resp., with KOH and EtOH, while avoiding admission of air as far as possible, and then spreading the mixt. in thin layers in the air. Or a mixt. of KOH and 2-aminoanthraquinone is spread out in the air and the defined quantity of alc. sprayed over it. The process may be carried out on an endless band and evapd. alc. recovered.

Brit., 20,793, Sept. 15, 1913. AKT.-GES. FÜR ANILIN-FABRIKATION. **Dyeing** furs, hairs, or the like by means of ammoniacal aq. solns. containing mixts. of aromatic *m*- or *p*-diamines with dihydroxy compds. of the benzene series and H_2O_2 or other oxidizing agent; the furs, etc., may be previously mordanted with $CuSO_4$, $FeSO_4$, dichromate, etc. Cf. C. A. 9, 2153.

Brit., 24,360, Oct. 27, 1913. BAYER & Co. **Dinitrophenylbenzidine- and -tolidinedisulfonic acids** are obtained by condensing a mol. of 2,4-(NO_2) $_2C_6H_3Cl$ with benzidine- or tolidine-2,2'-disulfonic acid. **Monoazo dyes** are obtained by combining the diazo compds. of the above described condensation products with salicylic acid, methyl- or ethylbenzylanilinesulfonic acids, pyrazolones with a free 4-position, *e. g.*, 1-Ph-3-Me-5-pyrazolone, acetoacetanilide, -toluidides, or -anisidides, or α -methylindol ϵ . The product from dinitrophenylbenzidine-2,2'-disulfonic acid and Me-4-sulfobenzylaniline is described in an example. The products dye wool yellow shades from acid baths.

Brit., 7,899, Mar. 28, 1914. A. EICHENGRÜN. **Fireproofing fibrous materials** by treating them both with a fireproofing agent such as tungstic, silicic, sulfurous, or boric acid or their salts, or phenylphosphoric acid, or the non-inflammable Cl derivs. of aniline, and with solns. of fatty acid esters of cellulose containing such agents. The fireproofing agents may be used in soln. or may be dusted on the fabrics, etc., and fixed. Cf. C. A. 8, 3124.

Brit., 7,916, Mar. 28, 1914. BAYER & Co. **Indigoid dyes** are obtained by condensing α -derivs. of halogen isatins or halogen naphthisatins, containing readily replaceable substituents such as the anilino group in the α -position, with 3-Ph-1-indanone or its homologs or substitution products; the isatin derivs. yield red vat dyes, and the 2,3-naphthisatin derivs. violet dyes. According to an example, α -anilino-5,7-dichloroisatin and 3-Ph-1-indanone are employed; α -anilino-5,7-dibromoisatin and 3-*p*-tolyl-1-indanone are also specified as initial materials.

Brit., 8,043, Mar. 30, 1914. BAYER & Co. **Trisazo dyes** are obtained by diazotizing an acyldiamine or nitroamine, coupling with α -naphthylamine or a deriv. thereof, re-diazotizing, again coupling with α -naphthylamine or a deriv. thereof, diazotizing again, coupling with resorcinol, and finally eliminating the acyl group or reducing the nitro group.

Brit., 8,355, Apr. 2, 1914. FARBW. v. L. DURAND, H. & Co. **White effects on cotton printed with gallocyanins or leuco compounds thereof** are obtained by first printing the fabric with a resist containing Cr phosphate and a Cr salt of an hydroxy-fatty acid such as citric, lactic, or tartaric acid. According to an example, cotton is printed with a resist consisting of $Cr(OH)_3$, citric acid, H_3PO_4 , glucose, British gum, China-clay, and stearin soap, dried, padded or printed with a gallocyanin, dried, steamed, and finished.

Brit., 8,365, Apr. 2, 1914. O. LUFFT. **Construction of an inter-communicating 2-compartment vat for dyeing, washing, bleaching, and otherwise treating textile goods** with a circulating reversible flow of liquor.

p-diaminophenylaziminobenzene, *p*-diaminodiphenyl ether, or homologs or substitution products thereof, with 1 mol. of an acidyl- β -aminonaphtholsulfonic acid and 1 mol. of resorcinol or a homolog or substitution product thereof. Cf. C. A. 9, 1549.

Brit., 8,666, Apr. 6, 1914. BAYER & Co. Monoazo dyes are obtained by combining diazotized aminoacidyl-*o*-aminophenolsulfonic acids (containing no carboxylic group) with pyrazolones or methylketol. Cf. C. A. 8, 3240.

Brit., 8,689, Apr. 6, 1914. BADISCHE. Indigo-white preparations are obtained by mixing together indigo-white, a paste-forming medium such as molasses or glycerol, and a solid organic substance, such as bran, flour, dextrin, wood, or sugar which assists fermentation; Zn dust may be added. According to an example, indigo-white is mixed with molasses and bran.

Ger., 282,278, Oct. 24, 1913. FARBW. v. M. L. & B. Mfg. alkyl ethers of indirubin oxime by allowing alkylating agents to act upon salts of indirubin oxime. Alkyl halides or sulfates, arylsulfonic acid esters, and the like are specified as suitable. The resulting alkyl ethers can be converted into valuable dyes. By the action of concd. H₂SO₄ red wool dyes are obtained.

Ger., 282,490, Feb. 27, 1914. BAYER & Co. Mfg. *N*-anthraquinonylsatins by allowing oxalyl chloride to react upon arylaminoanthraquinones, with the addition of condensation agents such as AlCl₃, Fe₂Cl₆ or P₂O₅. The resulting isatins form valuable initial materials for the production of dyes.

Ger., 282,493, Nov. 21, 1913. F. ÜLLMANN. Mfg. 4-halogen-1-hydroxyanthraquinones and their substitution products, by condensing phthalic anhydride or the like with *p*-halophenols or their substitution products, by means of AlCl₃. The resulting 5-halo-2-hydroxybenzoylbenzoic acids are converted then into the corresponding anthraquinone derivs. by the action of condensation agents.

Ger., 282,647, Apr. 28, 1912. Addition to 280,505 (C. A. 9, 1998). BADISCHE. Chromium compounds of hydroxyanthraquinonesulfonic acids and their derivs. are obtained, according to the principal process, from hydroxyanthraquinonesulfonic acids or their salts, etc., by treatment with Cr-oxide salts, in the heat. If conc. preps. are to be made by evapg., then mineral acid binding agents are added to the solns., before, during, or after the evapn. Bisulfite, silicic acid, glass powder (when employing fluorochrome), kieselguhr, etc., are specified as suitable additions.

Ger., 282,672, Mar. 14, 1913. FARBW. v. M. L. & B. Mfg. condensation products of the anthraquinone series or of their sulfonic acids by bringing into reaction with NH₃ or amines or aminosulfonic acids, with or without contact substances, the products of ethylene dihalides and alizarin obtained according to 280,975 (C. A. 9, 1999). The resulting color bases can be sulfurized.

Ger., 282,818, Dec. 24, 1913. FARBW. v. M. L. & B. Polychloroanthracenes are obtained by treating the Cl addition products of 9,10-dichloroanthracene in the presence of alkali benzylsulfanilates with aq. potash or soda lyes. The products are used as pigment colors, and serve as initial materials for intermediate products, e. g., chloroanthraquinone and dyes.

Ger., 282,889, May 3, 1913. Addition to 268,791 (C. A. 8, 2490). BAYER & Co. Monoazo dyes are obtained according to the principal process by coupling diazotized aminoacylamino-salicylic acids with azo dye components. By substituting the monoacylamino-salicylic acids by aminoacyl compds. of other *o*-aminophenols, their homologs and substitution products, and coupling the diazo compds. of these compds. with pyrazolones or their derivs., or with Me ketol, new azo dyes are obtained which yield bright, fast yellow shades on wool with chrome mordant.

Ger., 282,890, Nov. 9, 1913. KALLE & Co. Indigoid vat dyes are obtained by condensing hydroxythionaphthene, its substitution products, homologs or analogs, with hydroxyazo dyes which contain at least one heteronuclear substituted naphthol residue, especially oxycarbazole or aminonaphthol, as component. The resulting products are halogenated, if necessary. Cf. C. A. 8, 2491, 3242.

Ger., 282,920, Oct. 14, 1913. Addition to 281,010 (C. A. 9, 1847). AKT.-GES. FÜR ANILIN-FABRIKATION. In mfg. thioureas of the anthraquinone series, the urea of 3-aminobenzoyl-*o*-benzoic acid specified in the principal process is substituted by the corresponding thiourea. The product forms, with hydrosulfite and soda lye, orange dyeing vats, from which cotton is dyed in orange yellow shades fast to washing and Cl.

Ger., 282,957, July 15, 1913. BAYER & Co. Yellow wool dyes are obtained by coupling the diazo compd. of *p*-Cl-*o*-anisidine ($\text{Cl}:\text{NH}_2:\text{OCH}_3 = 4:2:1$) with alkyl-aralkylanilinesulfonic acids, such as Et or Me benzylanilinesulfonic acid.

Ger., 282,958, July 20, 1913. H. WEIL. Red wool dyes are obtained by oxidizing aminoaryl-*p*-sulfaminic acids together with *m*-hydroxydiarylamines. The resulting new oxidation products may be dyed out on wool from weak acid bath. They are, however, used as intermediate products for the manuf. of S dyes.

Ger., 283,066, Oct. 31, 1913. BADISCHE. Ketone-like condensation products are obtained by treating hydroxy derivs. of C_{10}H_8 with glycerol or similar agents in the presence of acid condensing agents (KHSO_4). The new products are valuable initial materials for the manuf. of dyes.

Ger., 283,103, Apr. 27, 1913. R. P. SMITH and G. E. DRUM. App. for dyeing, bleaching, and otherwise wet-treating textile materials. Cf. C. A. 8, 3373.

Ger., 283,137, Mar. 15, 1913. E. LEDERER and A. LEDERER. Black dyes are obtained by treating furfuran derivs. with S and an alkali, alk. earth or metal oxide. Wool, cotton, and other cellulose fibers are dyed directly by means of these dyes.

Ger., 283,181, Dec. 7, 1913. R. REXROTH. Device for use in dyeing cops.

Ger., 283,213, July 7, 1913. CHEM. FABRIK GRIESHEIM-ELEKTRON. Mfg. anthraquinone by treating anthracene in the presence of a solvent (e. g., glacial HOAc), first at temps. below 60° , with HNO_3 , and then converting the intermediate product to anthraquinone, in the presence of HNO_3 at higher temps. (90 – 105°). The product is exceptionally pure.

Ger., 283,482, Feb. 3, 1914. AKT.-GES. FÜR ANILIN-FABRIKATION. Mfg. di-anthraquinone oxides by heating α -nitroanthraquinones with alkali carbonates in indifferent solvents (PhNO_2). At first a portion of the nitroanthraquinone is converted into hydroxyanthraquinone which combines with nitroanthraquinone, with the splitting off of HNO_3 , to yield dianthraquinone oxide.

Ger., 283,632, July 8, 1914. R. KOPPISCH. Process and app. for collecting dyes running off with the H_2O in dyeing operations.

Ger., 283,690, Dec. 12, 1913. F. A. BAYER. Variegated designs on paper, textiles, and the like, by applying to the whole surface, or to portions thereof, a mixt. of colors of different sp. grs., and then passing the material over an uneven, heated cylinder or plate. The color is uniform where the material comes in contact with the raised portions of the roll, while the colors at other points do not mix.

Ger., 283,716, Dec. 24, 1912. Addition to 275,570. R. WEDDING & Co. Dyeing with mordanting-colors insol. in H_2O . Cf. C. A. 8, 1676.

Ger., 283,822, Mar. 3, 1914. K. KRANTZ. Treating textile materials with the elec. current for the purpose of bleaching, loosening, dissolving the fat, and cleaning them. The material is led over rolls through the electrolytic bath, back and forth, in such manner that between the reciprocating bands of material are suspended electrodes, which are connected alternately with the + and the - pole. If the salt and soda solns. composing the bath are decomposed by d. c., the deposits of saponified fats on the cathode, in increasing thickness, interfere materially with the treatment of the goods. This objection is overcome by using a. c.

26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

Studies of varnish with mirror condenser. P. POOTH. *Mikrokosmos* 3, 59-60 (1915).—Glass plates were covered with an enamel containing ZnO. When the plates were immersed in dil. H_2SO_4 , the ZnO was gradually dissolved, leaving a clear film. When this clear film was washed with H_2O and again treated with dil. H_2SO_4 , further quantities of Zn were detected in the soln. By a microscopic exam. of the clear film particles of ZnO were detected. Microscopic exams. were also made using the "Kosmos" mirror condenser. Treatment of films of ZnO enamels with dil. H_2SO_4 resulted in continual reduction in size of the particles of remaining ZnO until particles of "ultramicroscopic" size resulted. White enamel was thinned with turpentine and a drop of the clear, supernatant soln. was examd. under the microscope with transmitted light. No particles of ZnO were detected. With a dark field and mirror condenser a Brownian movement was seen in the drop. Although it cannot be stated with certainty that this movement was due to particles of ZnO, exam. of drops of varnish containing no ZnO showed no Brownian movement. The phenomena offer an interesting field for ultramicroscopic investigation.

E. W. BOUGHTON.

The resistance of modern lacquer products to alkalis. M. BOTTNER. *Kunststoffe* 5, 157-8(1915).—M. discusses briefly the prepn. and properties of enamel lacquers (e. g., ZnO, lithopone, and other compns. used in hospitals, schools, fermentation cellars, etc.). To det. resistance to alkalis a coat (on glass plates) several weeks old is exposed to the action of cold 10, 20, 25, and 30% solns. of Na_2CO_3 for 6, 12, and 24 hr. periods; finally the solns. containing the plates are warmed to 80-90°. Instead of the above procedure, the plates may be placed in 15 and 30% Na_2CO_3 solns. at 18° for $\frac{1}{2}$ -3 hrs., the temp. then slowly raised (about 30-35 min.) to 80-90°; in another test the temp. is rapidly (within 6 min.) raised to 100° (i. e., to the b. p.). After boiling a few min., the plates are placed in cold 30% NaOH soln. for 40 hrs.; the coat is then examd. as to gloss, color, etc. On washing off with cold H_2O no color should be dissolved or removed in the case of high grade products, which are designated "soda fast." To det. action of NH_3 , squirt 10 and 12.5% NH_3 solns. on the dry plates, cover with a watch glass, and let stand; if the coating after 3-4 hrs. is only slightly dulled on the wetted spots, the enamel is considered satisfactory. If the material softens so that it may be removed by rubbing with a glass rod, it is rejected. To det. resistance to NH_3 gas, an exposure of 15 min. suffices. The luster, color, etc., should not be affected by these treatments. It is noted that NaOH is used very little for cleaning these surfaces, but is used in 5 and 10% solns. as a disinfectant; in this case, the bacterial cultures, which have dried on the coated plate, are rubbed off with cotton wads moistened with 5% NaOH or other disinfectant. The "aspoil" color, white, of Rosenzweig and Baumann, Cassel, conforms to the above requirements and when applied to a smooth surface gives a hard and resistant coating (a substitute for tile). Oil colors, of course, cannot be used under alk. conditions.

F. W. SMITHER.

U. S., 1,147,848, July 27. C. ELLIS. Paint- or varnish-remover formed of light wood tar oil 50, C_6H_6 20, acetone oil 15, ceresin wax 3 and carnauba wax 0.5 parts.

U. S., 1,147,849, July 27. C. ELLIS. Paint- and varnish-remover formed of methylacetone 30, C_6H_6 25, glacial acetic acid 4 and ceresin wax 1 part.

H_2SO_4 4 parts, to effect condensation of the mixt., and then adding CCl_4 11, crude terpeneol 4, paraffin 1 and NH_4 acetate 0.5 part.

U. S., 1,147,971, July 27. R. S. PERRY. Rust-inhibiting coating for iron and steel; formed of a viscous asphaltic base mixed with 2-20% its wt. of dry finely powdered Na_2CrO_4 , K_2CrO_4 or a dichromate.

U. S., 1,148,851, Aug. 3. K. MIYAZAKI. Lacquered tin plate is made by cleaning the tin plate with dil. alkali soln., neutralizing and then applying alc. followed by a lacquer which readily solidifies and which contains a small % of shellac. After being kept in a humid chamber for 24 hrs. the plate is dried at 120-180°.

U. S., 1,148,908, Aug. 3. E. J. KOONTZ. Coating wood or other thin materials with pyroxylin mixtures. The material is first covered with paint which is allowed to dry, then a soln. of pyroxylin, camphor and amyl acetate is applied, followed by a second coat after the first has dried and a sheet of previously softened pyroxylin also coated with the same mixt. is cemented onto the coated wood.

Brit., 8,126, Mar. 31, 1914. A. FINKLER. A metallic paint is prepd. by mixing Zn white, white Pb, and Al in powder form, adding a spirit soln. of shellac to form a thin pulp, and then adding celluloid dissolved in acetone. Any desired color is obtained by adding pigment to the shellac soln.

Brit., 8,479, Apr. 3, 1914. ERZVERWERTUNGS GES. In treating ores containing ZnO for the production of Zn-bisulfite soln. from which zinc oxide is subsequently obtained, the crude material is treated with combined SO_2 , such as Zn-bisulfite soln., and when all the oxide has thus been converted into monosulfite, the whole is treated with SO_2 gas to dissolve the monosulfite. This avoids the slow action of free SO_2 on ZnO. The Zn-bisulfite soln. for starting the process may be obtained by treating some of the crude material with SO_2 in excess; but for subsequent use, some of the Zn-bisulfite soln. produced in the process is used. Two methods of working are described. In one, a part of the ore to be treated, say 1 ton, is treated with SO_2 to obtain dil. Zn bisulfite; a second ton of ore is then added, the bisulfite reacting upon the oxide to form monosulfite, and SO_2 gas is then passed in to produce bisulfite. Two tons more of ore are then added to produce monosulfite as before, which is treated with SO_2 gas, each further addition of ore being equal to the total amt. previously treated. In the other method, material containing monosulfite is passed through a tower in counter-current with SO_2 gas, the liquor as it leaves the tower being returned to the top of the tower through a mixer to which material contg. oxide is continuously added. When a sufficient concn. is obtained, the liquor is led off to pptg. app.; but a part may be reserved for mixing with the initial liquor, or the Zn is not completely pptd. to avoid the contact of free SO_2 with the oxide material.

Holl., 3,994, Dec. 31, 1913. DE BATAAFSCHE PETROLEUM MAATSCHAPPY. Mfg. drying oils from mineral oil by chlorinating the distn. products of mineral oil and heating with the addition of a catalyzer, preferably Zn. Unsatsd. compds. with strong drying properties are obtained.

27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

Manufacture of stearin without pressing. B. LACH. *Seifensieder-Ztg.* 42, 493-5 (1915).—A discussion of methods for obtaining stearin, among which are mentioned sepn. by means of differences in solubility in solvents such as alc., sepn. by centrifugals and sepn. by the "swetting process." The last-mentioned process consists in allowing the mass contg. stearin to stand at a temp. somewhat below its m. p. None of these methods is as good as the pressing method. E. SCHERUBEL.

Review of articles published in 1914 on fatty substances. G. FABRIS. *Ann. chim. applicata* 3, 349-71 (1915).—The topics reviewed include glycerides, fatty acids and their salts, general methods of analysis of fatty substances, vegetable fats and oils, animal fats, oils of marine animals, hardened or hydrogenated oils. S. LEVY.

Determination of the iodine number (Hübl index). ALFREDO PAGNIELLO. Turin. *Giorn. farm. chim.* 63, 505-15 (1914).—P. has studied the influence on the exactness of the detn. of the I no. of compds. such as $(\text{NH}_4)_2\text{CO}_3$ which are added to the $\text{Na}_2\text{S}_2\text{O}_8$ soln. in order to prevent decomp. of the latter. A soln. (A) was prepd. from 50 g. $\text{Na}_2\text{S}_2\text{O}_8$, 10 g. $(\text{NH}_4)_2\text{CO}_3$ and sufficient cold, boiled, distd. H_2O to give a vol. of 2 l., while a 2nd soln. (B) was prepd. in a similar manner with omission of the $(\text{NH}_4)_2\text{CO}_3$. The I no. of a series of fats (peanut, cottonseed, cod liver, sweet almond, hazel nut (roasted), poppy, tomato seed, castor, sesame and olive oils, suet, margarine and cacao, coconut and butter fats, etc.) was detd. by using each of the 2 solns. (A) and (B); the I no. indicated by the latter was in each instance considerably greater than that shown by the former. One g. $(\text{NH}_4)_2\text{CO}_3$ was found to be equiv. to 0.348 g. I (in the reaction between these compds. which takes place during titration with $\text{Na}_2\text{S}_2\text{O}_8$), so that 0.005 g. $(\text{NH}_4)_2\text{CO}_3$ (the amt. present in 1 cc. of soln. A) corresponds to 0.0017 g. I; 0.88 cc. of soln. A was, therefore, equiv. to 1.0 cc. of soln. B when referred to the same amt. of I in the titration of the blank (amt. of I present before reaction of the latter with the fat). Another error which is due to use of soln. A and which influences the final result in the same sense as the above is due to the action of $(\text{NH}_4)_2\text{CO}_3$ on fatty acids which may be present in the fat under exam. and also to the ready decomp. of $(\text{NH}_4)_2\text{CO}_3$ and consequent partial sapon. of the fat; in either case CO_2 is liberated and reacts with $\text{Na}_2\text{S}_2\text{O}_8$, thus increasing the titer. The influence of the foregoing 2 errors is well illustrated by the following example in which 37.35 cc. and 12.80 cc. of soln. B were required for titration of the original and residual amts. of I in the detn. of the I no. of a certain fat; the vol. of soln. A corresponding to the amt. of I absorbed was, therefore, 24.55 cc. The corresponding calcd. vols. of soln. A for the same wt. of the same fat were 32.86 cc. ($= 37.35 \times 0.88$) and 11.26 cc. ($= 12.80 \times 0.88$), resp.; the calcd. vol. of soln. A corresponding to the amt. of I absorbed was, therefore, 21.60 cc. The corresponding observed values of soln. A were, however, 33.00 cc. and 16.85 cc., resp., thus indicating a vol. of 16.15 cc. as equiv. to the amt. of I absorbed. The negative error due to reaction of $(\text{NH}_4)_2\text{CO}_3$ and I, therefore, appears to be const. in the titration of the blank, but is exceeded in the titration of the residual I by the positive error due to the action of $(\text{NH}_4)_2\text{CO}_3$ on fat and fatty acids, thus producing final errors in the titration of the original and residual I which act in the same sense and indicate a diminished

I no. When the method of the Swiss Pharmacopeia was used for detg. the I no. the indicated value of the latter was invariably greater when soln. A was used than when soln. B was employed. In this case the action of $(\text{NH}_4)_2\text{CO}_3$ on I, fats and fatty acids is prevented by the neutralizing action of the AcOH which is present, while the reaction between the latter and $\text{Na}_2\text{S}_2\text{O}_3$ is in turn impeded by the $(\text{NH}_4)_2\text{CO}_3$. The above discrepancy between the results obtained by use of solns. A and B is probably due to the excess of AcOH employed, the small amt. of fat which is used in the detn. and possibly to other factors. P., therefore, recommends that a simple soln. of $\text{Na}_2\text{S}_2\text{O}_3$ in distd. H_2O (freed from CO_2 by prolonged boiling and then cooled) be used for iodimetry in connection with detn. of the I no. of fats; this soln. should be protected from the light and kept in a cool place. The original method of Hübl, while requiring more time, is considered more exact than the modified methods which are often used. P. recommends the method employed by the chem. labs. of the Italian customs service (*Ann. lab. centr. Gabelle* 5, 394).

H. S. PAINE.

Emulsification and detergent action. S. A. SHORTER. *J. Soc. Dyers, Colourists* 31, 64-9 (1915).—A small amt. of oil shaken up with a much larger amt. of water will be broken up into small drops which will rise or fall through the water and coalesce to form a continuous mass of oil at the top or bottom when the shaking ceases. Addition of certain substances to the water modifies the process in 2 ways: (1) by preventing the coalescence of the oil into droplets, (2) by causing the oil to be split up into smaller drops by the same degree of shaking. Some emulsifying agents produce both of the above effects, others only the first. Emulsification is closely connected with the stability of bubbles and films. Plateau ascribes the property of forming durable films (1) to viscosity, (2) low surface tension of liquid; this explanation is unsatisfactory since many liquids with high viscosity and low surface tension do not form durable films, while the converse is sometimes true. Marangoni first gave an explanation in accordance with modern views, ascribing foaming power to a surface pellicle. In the case of a foaming soln. the surface pellicle is formed from the dissolving substance. If the addition of a solute lowers or raises the surface tension of the solvent, the solute will exist in higher or lower degree of concn. in the surface layers than in body of the soln. (proved by Gibbs). S.'s expts. with solns. of saponin, peptone, and albumin in the case of which a thickening of the surface layer proceeds for several weeks without sign of equil. indicates that the process is thermodynamically irreversible and, therefore, outside the scope of Gibb's theory. Donnan's explanation of how adsorption layers contribute to the stability of an emulsion by preventing the coalescing of 2 droplets of oil already emulsified when they collide with or touch a layer containing double the amt. of absorbed substance is unsatisfactory. The true explanation is that non-coalescence is due to the quasi-solidity of the surface layer. When a little olive oil is poured upon a dil. soln. of NaOH, long cylinders of oil are projected into the soln.; they become very thin and break up into small drops, the process of emulsification being almost spontaneous, due (1) to the rapidity of formation of soap layer, and (2) the plasticity of the layer. The stability of emulsions upon diln. depends upon the chem. reversibility of the process of adsorption. Alkali and soap emulsions are easily made but are unstable. Many colloids which form stable adsorption layers, will make an emulsion more stable if added to it. Other interesting problems connected with emulsification are: (1) the effect of concn. of the emulsifying agent on the emulsifying power, (2) the interchangeability of the inner and outer phases, *i. e.*, the possibility of emulsifying water or an aq. soln. in an oil. The study of detergent action involves not only the question of emulsification but also a knowledge of the properties of suspensions, such as d. of particles, elec. charge, and "Brownian motion." S. is conducting expts. to det. the relative parts played by the hydrolysis alkali and undecomposed soap in producing emulsification. Two sub-

stances are used, one pure benzene, the other benzene and oleic acid, and surface tension measurements and direct measurement of the emulsification power are made. Detn. already made show that though the addition of oleic acid to benzene lowers the tension against water it has no effect on the tension against soap soln.; therefore, hydrolysis alkali has no specific surface action similar to that exerted by ordinary alkali. S. hopes that expts. will lead to a standard method for detg. what may be termed "detergent neutrality of soap."

L. A. OLNEY.

Methods of purification of sulfide oils and of industrial oils in general. F. CANZONERI. Bari. *Ann. chim. applicata* 3, 344-9(1915); cf. C. A. 8, 3510.—Oils may be decolorized by special treatment alternately with animal C and Florida earth or fullers earth, or by agitating at intervals during 24 hrs., first with Al hydrosilicates and then with C, washing the product and filtering under pressure, taking account of the temp., the condition of the hydrosilicates and C, and the proper quantities. For strongly colored olive oils, called common or pressure oils, agitate with $\frac{1}{4}$ vol. NO in presence of H_2O (on the walls of the contg. vessel), later washing thoroughly with slightly alk. H_2O . Satisfactory results may also be obtained by warming the oil to 90-100°, and agitating strongly after adding about 0.5% K_2CrO_4 dissolved in a little H_2O , in presence of conc. HCl (5-6% of the wt. of the oil), washing and filtering. Oil so treated has a hardly observable yellow color and is not altered; no wt. is lost. The lower the acidity of the oil, especially of the sulfide oils, the less difficultly is it decolorized. High acidity also makes neutralization difficult; in such a case there is formed a slime of alk. salts that emulsifies the oil and hinders the sepn. Often the oil will dissolve the soap and retain it strongly. Before neutralizing with KOH or NaOH, it is best to reduce the acidity of high acid oils by mixing with oils of low acidity. The concn. of soln. and the temp. are important. Brine should be added to avoid emulsification. To prevent losses when emulsions have been formed, the residual masses are used in the subsequent operations. When the acidity of sulfide oils is above 50%, the NaOH process is inapplicable, but good results can be obtained by employing $Ca(OH)_2$ (7 parts to 100 parts oil) upon the oil heated to 120-50°, and successive extn. of the resulting slime with petroleum ether or better with acetone. Neutralization and decolorization can be performed simultaneously by treating the warm oil with the calcd. amt. of $Ca(OH)_2$ and 2-3% fullers earth or C. Industrial losses of the extractives must be guarded against by the use of closed and continuous systems.

S. LEVY.

Plant oils. M. RAFFO AND G. ADANTI. Bologna. *Boll. chim. farm.* 53, 33-6 (1914).—Detn. of viscosity as a criterion for oils may be more advantageously applied to the volatile fatty acids derived from the oils than to the oils themselves; the differences which are thus obtained are much more significant and the method may be employed for the detection of foreign oils which may have been added. The viscosity values of the most important plant oils are shown in 1 table, while in a 2nd table is shown the influence of added foreign oils on viscosity in a number of instances.

H. S. P.

Heating of cottonseed—its causes and prevention. E. H. R. BARROW. *J. Ind. Eng. Chem.* 7, 709-12(1915).—The presence of moisture is conducive to germination and hence to rise of temp. The presence of microorganisms is another cause of deterioration of the seed. The keeping qualities can be improved by allowing access of air but this requires too much storage space; drying so as to bring down the moisture content is also effective but expensive and if carried too far may even spoil the product. After expts. with various chemicals, including $FeSO_4$, $NaNO_3$, $CuSO_4$, Na_2CO_3 , $CaCl_2$, CH_3O , $MgCO_3$, $NaCl$, pipe clay, salicylic acid, $Na_2B_4O_7$, $H_2B_4O_7$, B. has worked out a process whereby heating and decompn. are prevented by the addition of NaCl. In this process the initial temp. of the seed must not be too high, and the NaCl must be finely divided, dry and loose. About 5% by wt. of salt is used but fully 75% of this is removed in

cleaning. As far as can be seen up to the present, there is no increase in damaged seed and no falling off in the available oil yields. The meal from treated seed is as good as that from untreated. Most of the NaCl is found in the hulls and lint; the effect on the hull is, therefore, beneficial as it lowers the amt. of NaCl which must be added to the fodder. The quality of the lint is also improved. The effect on the crude oil is still problematical.

ISADOR MILLER.

The fatty oil from the seed of *Styrax japonica*. HARUKICH OKADA. *J. Pharm. Soc. Japan* 1915, No. 400, 657.—The seed, pressed in the cold, yields 45% of greenish yellow fluorescent oil, having an acid no. of 1.1, a sapon. no. of 190.5 and a Hehner value of 94.7%. The solid acids consist of equal parts of stearic and palmitic, while the liquid acids are oleic and linoleic. The unsaponifiable substance crystallizes in glistening needles, m. 116°.

H. L. OLIN.

Production, botanical composition and volatile strength of American wild mustard seed. A. L. WINTON AND J. H. BORNHANN. *J. Ind. Eng. Chem.* 7, 684-6(1915).—The first part of the article contains a general discussion of the subject. In the second part, analytical data are given on 2 samples of charlock, 3 of pure brown mustard and 14 of commercial wild mustard seed.

ISADOR MILLER.

A new oil-bearing nut in the Philippines. ANON. *J. Roy. Soc. Arts* 63, 800 (1915).—A tree, not yet fully identified but believed to belong to the genus *Amoora* or *Dysoxylum*, produces a seed from which may be expressed about 45% of a dark, fatty oil, suitable for soap making. It is not a drying oil and is not edible.

E. H.

Soft soaps without potassium carbonate. J. B. *Speisensieder-Ztg.* 42, 493(1915).—Two formulas are given. Linseed oil fatty acids are used and K_2CO_3 is replaced by Na_2CO_3 .

E. SCHERUBEL.

Manufacture of Turkey red oil (ERBAN) 25. Edible Fats and Oils Section of the Swiss Food Regulations (KREIS) 12.

Brit., 7,670, Mar. 26, 1914. MÜLLER SPEISEFETTFABRIK AKT.-GES. A catalyst, particularly for converting unsatd. fatty acids or their glycerides into the satd. compds., is composed of Ni borate, or the substance obtained from Ni borate (e. g., Kahlbaum's prepn. $NiB_2O_4 \cdot 6H_2O$) by heating in dry H to 250-300°. Cf. C. A. 8, 1334.

28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

Decrease of sugar content of sugar beets on storage. G. FOTH. *Z. Spiritusind.* 38, 247(1915).—A sample of sugar beets of 14.9% sucrose showed only 9.8% after 5 months. The sample was well preserved and F. has no explanation for this great loss in sugar.

L. W. HAAS.

Determination of the viscosity of fillmasses. JOSEF ROUBÍNEK. Dobrovic. *Z. Zuckerind. Böhmen* 38, 578-87(1914).—Because of their great viscosity it is not practicable to det. the viscosity of fillmasses by means of viscosimeters based on the principle of the rate of flow. R. has, therefore, devised for this purpose a viscosimeter based on the principle of the detn. of the rate of free fall of a wt. through the liquid, the viscosity of which is to be detd. A hollow, flattened metallic ball weighing 150 g. is held by an attached, thick wire at a definite height through the action of an electromagnet; when the circuit controlling the latter is broken the ball falls through a definite,

const. distance (in this case 250 mm.). After falling this distance the ball is checked by means of a metallic disk (attached to the above mentioned wire) which comes in contact with a steel spring, thus closing the elec. circuit and actuating the electromagnet. An elec. light is flashed at the moment of closing the circuit so that the time of fall may be measured by means of a stop watch; a clock with elec. control may also be introduced in the circuit so that it is started and stopped at the moments of the beginning and end of the fall, resp. A H_2O -jacketed metallic vessel, 80 mm. in inside diam. and 240 mm. in height, is filled to a definite height with the fillmass and placed in a H_2O bath which is heated electrically to a const. temp.; the vessel containing the fillmass is placed directly beneath the ball when the latter is in an elevated position. After-product fillmasses which had been prepd. by boiling the sirup from the initial product and which had an av. actual quotient of purity of 76-79 were used for the 1st expts. The finally boiled product is usually stirred in the crystallizer for 4-7 days, the supersatn. coeff. and the viscosity being reduced by addition of calcd. amts. of H_2O at definite intervals during the course of crystn. so that the mother sirup has become molasses by the 7th day. The expts. were, therefore, planned so that the influence of both temp. and density on viscosity could be detd. The latter was detd. at 5° intervals between 90 and 55° inclusive for each definite diln. (6 in all) of the original fillmass with H_2O and the results were expressed in terms of the viscosity of the original fillmass at 90° (the temp. at which it entered the crystallizer) as unity. In addition it was possible to measure the viscosity of the 5th diln. at 50° and that of the 6th diln. at both 50° and 45° ; the viscosity at the other dilns. was too great for accurate measurement at temps. below 55° . The resulting data are both tabulated and expressed graphically; a composite curve showing the influence of changes of both temp. and density on viscosity during the course of crystallization is also given. The influence of temp. on viscosity is greatest at lower temps., an abrupt increase in viscosity taking place (with decreasing temp.) at approx. 75° ; in order to promote crystn. it is especially necessary, therefore, to add H_2O to the contents of the crystallizer at temps. under 75° . The temps. at which it is desirable to add H_2O in order to maintain the appropriate viscosity for rapid crystn. may readily be detd. from the tabulated data. Addition of H_2O may be avoided by employing a lightly boiled sirup, but in this case an insufficient boiling effect is obtained and the results are not so satisfactory. In case it is desired to obtain a molasses of approx. 60 coeff. of purity from a sirup with an actual coeff. of 77-80, it is necessary to reduce the coeff. of the mother sirup of the fillmass to 66-68 by boiling *in vacuo*; in this case the molasses would show an actual coeff. of 60-61 and an apparent coeff. of 58-60. On diln. of the boiled product to 10-11%, the coeff. of the mother sirup would be increased to 70 and a molasses with a quotient of 63 would be obtained; this is the disadvantage of the use of lightly boiled sirups. Various analytical data of the fillmasses and mother sirups (the viscosity of which had been detd.) are tabulated so as to be correlated with the temp. in the crystallizer, the duration of stirring and the time at which H_2O was added (also the amt. of the latter employed).

H. S. PAINE.

U. S., 1,149,067, Aug. 3. P. KESTNER. Brazilian or "areado" sugar is produced by flowing melted sugar containing a small % of H_2O in a thin layer over a horizontal plate or endless belt which is rapidly vibrated longitudinally while the sugar is allowed to solidify on it.

29. LEATHER AND GLUE.

Sumac industry in Sicily. E. ASCIONE. *L'industria* 29, 227, 253, 261, 278, 297 (1915); *Ann. chim. applicata* 3, 376(1915). S. LEVY.

Some chromium salts used in tanning. M. MARCHIONNESCHI. *Ann. lab. chim. cent. delle Gabelle* 7, 249(1914); through *Ann. chim. applicata* 3, 374(1915).—The author treats of combinations of basic Cr sulfates with Na_2SO_4 . S. LEVY.

Manufacture of technical fermented lactic acid, the so-called "leather lactic acid." W. HOFFMANN. *Chem. Zig.* 39, 525-6(1915).—H. gives directions for making the sugar from starch, the prepn. of the cultures, the carrying out of the fermentation and the purification and concn. of the acid. Cf. *C. A.* 4, 1648; 7, 2647. J. H. MOORE.

Brit., 7,467, Mar. 24, 1914. F. HIRSCH. Addition to 5,863, 1914 (*C. A.* 9, 2325. **Chrome tanning.** See Ger., 274,549 (*C. A.* 8, 3136).

Brit., 8,028, Mar. 30, 1914. BADISCHE. Decolorizing or bleaching leather by treating it with a synthetic tanning agent of the aromatic series described in one or other of the specifications 8,511, 1912 (*C. A.* 7, 3251), 24,216, 1912 (*C. A.* 8, 1357), 7,137, 1913 (*C. A.* 8, 2780), or 18,258, 1913 (*C. A.* 9, 393). In examples: (1) leather impregnated with darkly colored tanning agents is suspended in a soln. of the product obtained according to example (2) of 7,138, 1913 (*C. A.* 8, 2638) for a time sufficient to bleach or decolorize it, and is then washed, as by passing through lukewarm H_2O , and dried slowly in the dark; (2) leather which has been well exposed to the air and dried is brushed with the soln. of example (1) above, washed, and dried as before; (3) leather is suspended in a sumac ext., to which has been added a soln. of the product obtained according to example (2) of 24,216, 1912, for some time, and then washed and dried in the dark.

30. RUBBER AND ALLIED SUBSTANCES.

R. T. STOKES.

The presence of acetaldehyde and hydrocyanic acid in the latex of *Hevea brasiliensis* Müll. Arg. M. KERBOSCH. Tjinjirean. *Rec. trav. chim.* 34, 235-8(1915).—The fresh latex has a peculiar odor and expts. were made to det. the nature of these volatile substances. Three l. of the fresh latex having an acid reaction were steam-distd. to obtain 300 cc. of distillate. If the latex was not acid, tartaric acid was added before the distn. The 300 cc. were again distd. and the first 30 cc. tested at once. The distillate was neutral, and gave the fuchsin + SO_2 test for aldehydes, reduced $\text{Ag}_2\text{O}-\text{NH}_3$ soln., Fehling soln., and Nessler reagent, gave CHI_3 with $\text{I} + \text{KOH}$, a blue color with Na nitroprusside and piperidine, and Lewin's test (*Ber.* 32, 3388(1899)) for AcH. With $p\text{-O}_2\text{NC}_6\text{H}_4\text{NHNH}_2$ it gave a *p*-nitrophenylhydrazone, m. 128° , which is identical with that of AcH. The amt. of AcH in 3 l. corresponds to 0.0017 g. Heretofore AcH has been found very rarely in nature. It has been found by Blanksma (*C. A.* 8, 359) in the prepn. of certain essential oils and associated with EtOH in the green parts of plants under anaerobic respiration. The filtrate from the hydrazone was neutralized with CaCO_3 and the distillate examd. for EtOH; none was found. The AcH is, therefore, not a product of anaerobic respiration. Rosenthaler (*C. A.* 8, 2410) states that CH_3O and AcH are products of oxidation of a number of substances occurring in plants, like rhamnose and lactic acid. K. does not think that AcH could be formed by oxidation in this case, for it would be difficult to explain why the easily oxidizable caoutchouc is not oxidized also. The latex obtained while the leaves were falling contained less AcH. Gorter (*C. A.* 6, 3310) found phaseolunatin in the seeds of *Hevea*,

which led K. to test for AcH and HCN in the latex. The fact that the hydrazones obtained melted at 128° , and when mixed with the same deriv. of acetone (m. 148°) showed a sharp lowering of the m. p., indicated that acetone was absent. The presence of HCN was shown by the Prussian blue test. E. J. WITZEMANN.

Ger., 282,817, Jan. 3, 1912. BAYER & Co. Mfg. erythrene or its homologs and analogs by breaking down the double mols. of these hydrocarbons, in the undild. state, excepting dipentene, by heating, if necessary, with the addition of suitable catalyzers. E. g., the double mol. of α -Me-butadiene is gasified, drop by drop, and the vapors are conducted through a tube heated to $500-700^{\circ}$, α -Me-butadiene collecting in the receiver. Ag gauze, Cu gauze, or Pt wire mesh may be used as catalyzers. The heating can be effected catalytically. Cf. C. A. 9, 833.

Ger., 283,162, Sept. 20, 1913. Addition to 251,217 (C. A. 7, 427). BAYER & Co. Erythrene is obtained, according to the principal patent, by the breaking down of petroleum or petroleum fractions or residues, with the aid of hot contact bodies, etc. Better yields, are obtained when the heated contact bodies are placed in the liquid petroleum. Elec. heated contact bodies are used. Cf. C. A. 9, 1136.

CHEMICAL ABSTRACTS

Vol. 9.

OCTOBER 10, 1915.

No. 19.

I. APPARATUS.

L. C. JONES.

The development of the Bunsen burner. A contribution to the history of the laboratory heat supply. A. KISTNER. Karlsruhe i/B. *Chem. App.* 2, 185-7(1915).

J. H. MOORE.

A study of the quality of platinum ware. GEORGE K. BURGESS AND P. D. SALE. *Bur. of Standards, Sci. Paper No. 254*, 28 pp.(1915); *J. Ind. Eng. Chem.* 7, 561(1915).—A method is given for detg. the purity of Pt ware without injuring in any way the article tested (cf. *C. A.* 8, 2539). The loss of wt. of a crucible upon heating was detd. by use of a graphite, porcelain-lined, elec. heated furnace at 1200°, the crucible being subjected to heating periods of 2 hrs., before and after which careful weighings were made. The loss of wt. per 100 sq. cm. of practically Fe-free crucible surface at 1200° ranged from 0.71 to 2.69 mg. per hr., the smaller losses referring to crucibles containing Rh and the larger losses to those containing Ir. Fe as impurity decreases the rate of loss of wt. but its presence is objectionable on account of the formation of the sol. oxide. Detns. of magnetic susceptibility did not give satisfactory indication of Fe content. It appears possible, however, by use of the tables and curves given, and by a simple thermoelec. and microscopic exam. of a crucible, to predict its probable loss of wt. on heating closely enough for analytical purposes. A good crucible should be of Pt with 3 to 5% Rh for stiffening, practically free from Fe and Ir, and containing no other detectable impurities. If these requirements are met the e. m. f. at 1100° against pure Pt is less than 8 and more than 5 millivolts (cf. *C. A.* 8, 2539). The cryst. structure as shown under the microscope is clearly that of Rh and not Ir, and chem. test of the surface of the crucible, after heating 2 hrs., fails to show presence of Fe.

PAUL D. FOOTE.

Gas wash bottle with several distributing tubes. ANON. *Z. angew. Chem.* 28, I, 316(1915); see fig.—To overcome disadvantages of T-tube connections, unequal pressure and irregular distribution of gas (e. g., H_2S), the app. shown in the cut was devised. Tube *a* is attached to the gas generator and connections are made at *b, b*. The distance between the inlet and outlet tubes is equal in each case, permitting a uniform pressure at all cocks.

F. W. SMITHER.

Apparatus for the study of reactions between gases and liquids. E. E. REID. *J. Am. Chem. Soc.* 37, 2112-4(1915).—The app. devised permits of introducing a highspeed stirrer inlet and outlet tubes and, if desired, a sampling tube through a comparatively small stopper, the whole being made gas-tight for both moderately increased and diminished pressures by means of a mercury seal. It has been satisfactorily used at temps. up to 220° with the stirrer revolving at the rate of 3000-4400 r. p. m. under a pressure of 3 ft. of H_2O .

CHAS. A. ROUTLER.

A thermobalance. KOTARO HONDA. *Sci. Repts. Tohoku Imp. Univ.* [2] 4, 97-103 (1915); 2 plates.—The balance is designed to study changes in wt. which are due to changes in temp., both wt. and temp. being measured during the change. The app. consists of a balance beam with silica-glass arms and central agate knife edge and plate: At one end of the beam a thin porcelain tube is rigidly attached, hanging vertically. It holds a Pt cup and extends into a small, porcelain tube, Pt-wound, elec. furnace. The height of the furnace is adjustable with rack and pinion and it has a Ni tube lining to secure even distribution of heat. At the other end of the balance is attached a spiral spring which is immersed in an oil bath in a Dewar flask and attached to the bottom of the flask. Thus the temp. of the spring is const. The flask is mounted on a system of levers, similar to a level trier, so that its vertical movement is controlled and measured by means of a micrometer screw and scale. The deflection of the balance beam is measured by mirror, telescope and scale; its motion is damped by a cylinder, with central partition, immersed in oil. Scale pans over either end of the beam allow for control and calibration. Within small limits the deflection of the beam may be used to measure changes in wt.; for greater accuracy, the null method, by raising or lowering the Dewar flask through measured distances. A Pt-PtRd thermocouple is inserted, through the thin porcelain tube, in the Pt cup in the furnace. Its cold junction is just above the central knife edge. Connection is made to the galvanometer by means of weak copper spirals, extending out from the beam on either side at right angles. Measurements were made on the dehydration of $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$; dehydration and decompn. of $\text{MgSO}_4 \cdot 4\text{H}_2\text{O}$; decompn. of CaCO_3 ; of the change of structure of CrO_3 at high temps. $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ begins to lose H_2O at 130° and is dehydrated by 260° . The rate of loss is about 0.0992 g. per hr. $\text{MnSO}_4 \cdot 4\text{H}_2\text{O}$ loses 3 mols. H_2O between 70° and 110° , the other mol. between 230 and 260° . The decompn. begins at 820° and is complete at 950° . Observed and calc. results agree within 2 to 5%. CaCO_3 begins to decompose at about 500° , the rate increasing with rise in temp.; it reaches a max. at 820° and terminates at 880° . Observed and calcd. wts. agree within 2.5%. The changes in CrO_3 take place as follows: $80\text{--}100^\circ$, slight loss due to moisture; $320\text{--}340^\circ$, $\text{CrO}_3 \rightarrow \text{Cr}_2\text{O}_3$; about 405° , $\text{Cr}_2\text{O}_3 \rightarrow \text{Cr}_2\text{O}_5$; 460° , $\text{Cr}_2\text{O}_5 \rightarrow \text{Cr}_2\text{O}_7$. In this last case the quant. agreement is not very good. F. A. HARVEY.

Heusser multiple weight attachment for chemical balances. W. HEUSSER. *Eng. Mining J.* 100, 314 (1915).—The balance, explained by illustrations, was designed to eliminate the tedious task of picking up and placing small wts. upon the pans, and arresting the balance each time for the purpose. The pan hanger on the right side carries a perforated plate or grid; back of this hanger a short column is solidly mounted upon the base plate, carrying 9 movable levers. The front end of each of these levers has an upright conically tipped staff, which moves centrally and vertically through the perforations of the grid. The levers are operated from the outside by means of depressible push keys arranged similarly to a typewriter keyboard and located in front of the balance. The wts. are in the form of disks, each having a central perforation. At rest they are supported by means of the conically tipped staffs, which extend partly into the perforations. When in use they are deposited in countersunk holes in the grid. These wts. may be deposited and again picked up independently of each other, and the balance-beam is free to swing, by simply pushing the depressible keys up and down. The value of each wt. is plainly marked upon an index plate placed above the keyboard, and the possibility of making mistakes is positively excluded. The capacity of the wts. for assay balances is 221 mg. and is divided into 1, 2, 3, 5, 10, 20, 30, 50 and 100 mg. For extremely delicate weighings (using 0.5 mg. rider), the capacity is only 110 mg. It is claimed that these balances will save 50% of the time consumed in weighing with an ordinary balance. For analytical balances, the wts. are 10 times heavier, or 2210 mg. in all. F. W. SMITHER.

Convenient weighing pipet. FRANK HALL. *J. Am. Chem. Soc.* 37, 2062-3(1915).

—An ordinary pipet body was fitted with a stopcock at the bottom, close to the main bulb, and a short neck of thick-walled glass with a small bulb blown in it. This bulb served as an overflow when filling, and prevented the neck from slipping through the supporting hook which hangs from a balance arm. E. B. MILLARD.

Simple apparatus for determining the melting point of substances which are poor conductors of electricity. IGNACIO GONZÁLEZ MARTÍ. Madrid. *Anales soc. españ. fis. quim.* 13, 160-2(1915).—A Cu vessel *A* is attached by means of a screw clamp to an upright rod *T* which is supported in an Fe base. An Fe vessel *B* is supported within the vessel *A* by 3 thick wires (attached radially to *B* at the top) which rest in notches in the upper rim of *A*. A thermometer and a Cu wire *V* 3 mm. in diam. are supported by a clamp attached to an upright rod *S* which is inserted in the same base as the rod *T*; the thermometer and wire pass nearly to the bottom of *B*, but do not touch the latter. Binding posts *M* and *N* inserted in the metallic base near *S* and *T*, resp., are connected with the wire terminals of an elec. circuit containing an elec. bell and storage battery or cells. The vessel *A* constitutes the heating bath and is filled with an appropriate liquid; *B* is almost completely filled with Hg and the wire *V* is coated (e. g., by dipping in the fused mass) with the substance the m. p. of which is to be detd. If this substance is a poor conductor of electricity the circuit remains open. The bath *A* is then heated and when the substance melts the circuit is closed by contact between the wire *V* and the Hg in *B*, thereby causing the bell in the circuit to ring; at this signal the thermometer is immediately read. H. S. PAINE.

Apparatus for hastening evaporation. B. FREEMAN. *Chem. Analyst* 14, 11(1915).—A current of air is passed through a coil of block tin tubing in a water bath, and allowed to blow across the surface of the liquid to be evapd. H. M. LANCASTER.

Platinum baskets for use in combustion furnaces. W. G. GRANT. *Chem. Analyst* 14, 24-5(1915).—Sheet Pt can be cut and folded into the form of a frustum of a hollow cone. The base is covered by folding in part of the wall, thus forming a conical vessel which can be filled with ignited asbestos. A glass tube is then closely fitted to the small end of the cone, and passed through the perforation in the stopper of a combustion tube, the Pt remaining just inside to protect the stopper. H. M. L.

Plug for combustion furnace. R. S. COCHRAN. *Chem. Analyst* 14, 9(1915).—To protect the stopper of the ordinary horizontal combustion tube, a plug of asbestos is much better than loose fibers. Moisten some ordinary asbestos with water, and squeeze in the hand into a roughly cylindrical form about 1.5 in. long and of same diam. as the tube. Wind a doz. turns of Nichrome wire (No. 4, B & S) in a spiral around the asbestos, and then about 10 turns lengthwise. Make a small loop at one end to serve as a handle. The finished plug slips loosely into the tube. H. M. L.

Flicker photometer attachment for the Lummer-Brodhun contrast photometer. E. F. KINGSBURY. *J. Frank. Inst.* 180, 215-23(1915).—Chiefly details of construction of a flicker attachment to replace the telescope of the ordinary L.-B. contrast photometer when it is desired to measure differently colored lights. A discussion of photometers in general has been included. E. B. MILLARD.

Practical apparatus for the filling of ampoules without employing a vacuum. MURAT AND A. LACOSTE. *J. pharm. chim.* 12, 22-4(1915).—Ampoules holding either 1 cc. or 1.5 cc. are filled from a 10 cc. buret on the principle of communicating tubes through a bent capillary tube in one piece with the buret. A reservoir tube is also attached to the latter, and one stopcock regulates the filling of the buret, another that of the ampoule. S. WALDBOTT.

Home-made still. ANON. *Elec. World* 66, 366(1915).—A 12-in. Fe pipe, flanged,

headed and set upright upon a tripod forms a cooler for a 35 ft. Cu coil. Cooling H_2O enters at the bottom and the overflow is near the top. The Cu coil, 10×35 , inside of the Fe pipe connects at one end to the station steam-header carrying 175 lbs. Valve adjustment in the steam and cooling H_2O lines regulates the flow of pure H_2O . A diagram is given.

W. H. BOYNTON.

Vacuum pans (KERR)₄28.

U. S., 1,147,706, July 27. W. R. CLYMER. Furnace for calcining granular carbon or other materials. The charge to be calcined passes from the hopper 3 downwardly through the vertical shafts 2 which are heated by burning gases produced from the charge itself, circulated through the passages 8, 10 and 15 by a blower, 12, or by gas from an outside source.

U. S., 1,148,259, July 27. F. SPARRE and W. E. MASLAND. Apparatus for chlorinating saturated hydrocarbons. The liquid to be chlorinated is charged with Cl in an opaque absorption chamber, then led through a series of glass tubes in which it is exposed to a Hg vapor light. HCl formed is recovered in an absorption tower.

U. S., 1,148,364, July 27. C. A. DUNCAN and G. L. SHOUP. Acetylene generator.

U. S., 1,149,440, Aug. 10. F. B. HAYS. Milk bottles or other receptacles are made by satg. sawdust with Na silicate soln., molding and pressing the jelly-like mass formed, slowly drying and then waterproofing with paraffin.

U. S., 1,148,501, Aug. 3. C. G. COLLINS. Apparatus for separating sulfur or other suspended solids from gases or fumes. See fig. Gases introduced through the pipe 2 are passed successively through the compartments which are sepd. by the vertical baffle plates 4. Each of these compartments is nearly filled by a body of filtering material, *e. g.*, excelsior or asbestos, held within a cage, and the cages are alternately agitated by rods operated by cams 10 on the shaft 9, causing the deposition of the sepd. solids in the bottom of the app.

U. S., 1,150,730, Aug. 17. W. BANWARTH. Acetylene generator.

Brit., 8,725, Apr. 7, 1914. J. S. OWENS. In testing air, an app. for measuring the amt. of suspended matter comprizes aspirating appliances, a filtering app. in which the filtering-member is a disk of paper of standard size, and a scale of shades of color for comparison with the discoloration produced on the filtering disk.

Brit., 9,344, Apr. 15, 1914. F. HABER and R. LEISER. Gas testing apparatus, for detecting variations in compn., comprizes 2 organ pipes of the closed labial type which are blown by the same gas current, one of the pipes being provided with a membrane and enclosing a vol. of a standard gas, and the other pipe being provided with

a membrane or not, and containing the gas to be tested. The variations in compn. in the gas are detd. by the "beats" when the pipes are sounded together.

Brit., 9,643, Apr. 18, 1914. N. G. BITHRIE. A filter for oil comprizes a chamber divided by a horizontal filter into 2 compartments, from the lower of which the oil is forced through the filter by H_2O introduced under pressure.

An interesting application of chemical theory. Presented to the Academy of Padua in 1788. G. BRUNI. *Atti Accad. Padova* 31, 3-4(1915).—Historical note.

L. T. FAIRHALL.

Choice of standard weights for elements. J. WADDELL. *Chem. News* 112, 50-2 (1915).—Explanation of the choice of at. wts., law of multiple proportions, etc., written "with a view of helping students, and possibly teachers also." E. B. MILLARD.

Interpretation of molecular weight results from measurements on solutions (with special reference to a paper by Beckmann and Maxim). W. E. S. TURNER. *J. Am. Chem. Soc.* 37, 2063-4(1915); cf. B. and M., *C. A.* 9, 1570.—T. objects to the statement by B. and M. that change of temp. (between 75.4° and 54.1°) had but little effect on the degree of association of $PhOH$ in CCl_4 , and that at the f. p. of CCl_4 (-23°) the degree of association was distinctly greater than at the higher temps. Since the change of dielectric const. with the temp. would tend partially to counterbalance an apparent change in association, the true effect cannot be ascertained. It will probably be greater than supposed by B. and M. Their results are in harmony with the rule that the higher the dielectric const. of the solvent the smaller the degree of association of the solute.

E. B. MILLARD.

Atomic weight of cadmium. G. A. HULETT AND E. L. QUINN. Princeton Univ. *J. Am. Chem. Soc.* 37, 1997-2000(1915); cf. *C. A.* 5, 1881; 7, 2149; 8, 845; Baxter and Hartman, *C. A.* 9, 735.—The paper is largely a reply to B. and H. on their criticism of the work of H. and Q. The test for Cd was not made in the presence of an excess of H_2SO_4 , and test expts. carried out with 0.00005 g. Cd in the presence of excess H_2SO_4 showed that the latter was so completely removed as not to interfere with a positive test with H_2S . This would lead to an error not greater than 1 in 100,000. Test expts. with the purest Cd dissolved in HCl and electrolyzed in the H. and Q. cell (amalgamated Pt) checked to ± 0.00004 g. The % Cd in $CdCl_2$ was 61.217 with a probable error of not over 0.002%. The Ag coulometer used was not at fault; inclusions in the deposit varied about 0.5 in 100,000 and were taken into account in computing the at. wt.

E. B. MILLARD.

Atomic weight of molybdenum. J. H. MÜLLER. *J. Am. Chem. Soc.* 37, 2046-54 (1915).— MoO_3 was converted to $(NH_4)_2MoO_4$ and 5 times recrystallized, volatilized in HCl gas, the middle portion was again converted into $(NH_4)_2MoO_4$, evapd. and ignited in quartz, fractionally sublimed in air, then again in HCl at 250° , dissolved in H_2O , added to NH_4OH in Pt dishes, ignited, and the latter sublimation repeated 4 times. This oxide was reduced to metal in a stream of carefully purified H in a quartz boat. The special quartz reducing app. was heated to 1000° by gas flames in a furnace. Sp. gr. detns. of Mo gave $d_{20}^{20} = 10.281$, and of MoO_3 , $d_{20}^{20} = 4.696$ as means of 3 expts. in pure toluene. The final MoO_3 was divided into 3 fractions, from which 9 samples of reduced Mo were finally obtained. These were reduced to const. wt. ± 0.00002 g. after heating about 20 hrs. in H at 1000° . The samples (averaging about 1 g. each)

were carefully oxidized, first in air, and finally in O, to MoO₃. As a mean of all 9 expts. the at. wt. Mo = 96.035 was obtained. Omitting one expt. on which the least confidence was placed, Mo = 96.029. It was shown that Mo does not absorb weighable quantities of H.

E. B. MILLARD.

Allotropic modification of lead. H. J. M. CREIGHTON. *J. Am. Chem. Soc.* 37, 2064-5(1915).—The observation of a gray modification of Pb by Heller (*C. A.* 9, 2339) has been confirmed by an expt. in which the powdery gray Pb appeared on a cathode in a soln. of HNO₃ after passing 2-3 amps. at 6 v. for 8 hrs.

E. B. MILLARD.

Solubility product constants of calcium and magnesium carbonates. JOHN JOHNSTON. *J. Am. Chem. Soc.* 37, 2001-20(1915); cf. Stieglitz, *C. A.* 3, 1740.—These consts. have been recomputed for calcite and MgCO₃·3H₂O from the best data available; the results are satisfactorily concordant over a partial pressure of CO₂ varying 10000-fold for CaCO₃. The recalculated results are: $[Ca^{++}][CO_3^{--}] = 0.98 \times 10^{-8}$ at 16° when the soln. is satd. with respect to calcite; $[Mg^{++}][CO_3^{--}] = 1.93 \times 10^{-8}$ at 12°, the soln. being satd. with MgCO₃·3H₂O; $[Ba^{++}][CO_3^{--}] = 7 \times 10^{-9}$ at 16°, the solid phase being BaCO₃. The solubility-product const. of MgCO₃·3H₂O at temps. up to 50° is $\log K_{Mg} = (2315/T) - 11.870$, which corresponds to MgCO₃·3H₂O = Mg⁺⁺ × CO₃⁻⁻ + 3H₂O + 10600 cal. evolved. CaCO₃ pptd. from solns. contg. Mg will probably be contaminated with it. Mixtures of Mg(OH)₂ and MgCO₃ will generally be obtained in pptg. Mg by a carbonate, and these basic carbonates are merely indefinite mixtures of carbonate and hydroxide. Both MgCO₃ and CaCO₃ can be obtained free from contamination by keeping the partial pressure of CO₂ above a certain limiting value which need not be greater than 1 atm. under suitable conditions of pptn. The const. $[HCO_3^-]^{1/2}/[CO_3^{--}][H_2CO_3]$ was 5600 *n* at 25°, where *n* (which is probably greater than 0.5) is the proportion of the total CO₂ in soln. which exists as H₂CO₃. There can be no real equil. in aq. solns. of carbonates except in the presence of a definite partial pressure of CO₂ in the atm. in contact with the soln.

E. B. M.

Vapor pressure of liquids in the presence of gases. F. H. CAMPBELL. *Trans. Faraday Soc.* 10, 197-206(1915).—The method of *C. A.* 9, 402-3 has been applied to ether, acetone, CS₂, MeOH, EtOH, and H₂O at temps. varying from 20 to 70°, in the presence of H₂, CO₂, air, and the satd. vapor of the liquid. Only 1 expt. has been made for each substance at a given temp. Et₂O has been measured at 2 temps., the other substances at 1 temp. each. The pressures are lowest in an atm. of CO₂, greater in air and H₂, and greatest in the absence of gases other than the satd. vapor. With any one gas, the lowering is related to the solvent power of the liquid. The amt. of gas dissolved was not sufficient to account for the observed differences, and the differences tend to disappear when the liquid is violently agitated. The concn. of a gas in the surface layer of an unstirred liquid was thought to be greater than that in a part of the liquid away from the gas.

E. B. MILLARD.

Vapor pressures of propane, propylene and normal butane at low temperatures. G. A. BURRELL AND I. W. ROBERTSON. *J. Am. Chem. Soc.* 37, 2188-93(1915).—Using the same method as in the earlier paper (*C. A.* 9, 2583), the vapor pressure of propane was found to range from 760 mm. at -44.1° to 3 mm. at -124.2°; that of propylene from 760 to 3 mm. at -47.8° and -127.4°; that of *N*-butane from 760 to 1 mm. at -0.3° and -99.9°, resp.

CHAS. A. ROUILLER.

Density and degree of dissociation of the saturated vapor of phosphorus pentachloride. ALEXANDER SMITH AND R. H. LOMBARD. *J. Am. Chem. Soc.* 37, 2055-62(1915).—The app. was the same as that used on NH₄Cl, etc. (*C. A.* 9, 748). Expts. in sets of 4 or 5 were made at 7 temps. between 90° and 160°. The wt. of PCl₅ in a large bulb which had been in equil. with liquid PCl₅ was detd. by pptg. the Cl as AgCl.

Above 110° the exptl. curve of vapor d. against temp. was practically parallel to the theoretical curve (assuming no dissociation) and slightly below it. At 90° and 100° the vapor appears to be slightly associated; it is dissociated to an approx. const. extent of about 4% from 110° to 160° . The latent heat of evapn. was calcd. as 15500 cal. per mol. An additional expt. on NH_4I (cf. C. A. 9, 748) confirmed the first conclusion that satd. NH_4I vapor is partly associated.

E. B. MILLARD.

Adsorption of acetylene by colloidal platinum, iridium and osmium, and by platinum black. C. PAAL AND A. SCHWARTZ. *Ber.* 48, 1195-1202(1915); cf. C. A. 7, 1312.—The Pt sols used contained 0.1 and 0.2 g. Pt per 10 cc. and an equal amt. of a protective colloid, Na protalbuminate. Adsorption proceeds rather rapidly at first, and becomes slower and slower as satn. is approached, because the adsorbed C_2H_2 forms liquid or solid condensation products which surround the metal particles, at first diminishing its adsorptive power, and finally destroying it entirely. New expts. on the adsorption of C_2H_2 by Pt black gave very much smaller values than those in the earlier expts. (*Ber.* 37, 126 (1904)), though the values were far from concordant. The amt. adsorbed by 0.5 g. Pt black was 10.51 cc.; that by 0.25 g. was nearly as much as for 0.5 g., namely 9.09 cc. Os and Ir hydrosols did not adsorb C_2H_2 in measurable quantity.

E. B. MILLARD.

Interpretation of maxima on viscosity curves. S. ENGLISH. *Chem. Trade J.* 56, 488(1915).—The accepted interpretation that viscosity maxima indicate mol. compds. and minima are due to mutual dissociation has been cast into doubt by recent work. This simple explanation of the deviations from the mixture law is inadequate, for, though mixts. of H_2O , MeOH and EtOH with HCONH_2 give sagged curves, n - PrOH gives a sinuous curve and n - BuOH and *iso*- $\text{C}_4\text{H}_9\text{OH}$ give curves contg. both maxima and minima. This would indicate that HCONH_2 combines with n - BuOH and *iso*- $\text{C}_4\text{H}_9\text{OH}$, but not with the lower, more active alcs. F. p. measurements show that in the case of mixts. of the lower aliphatic acids with HCONH_2 , there is no close agreement between the indications of the equil. diagrams and the viscosity curves. HOAc and HCONH_2 have a viscosity max. at 66 mol. % but form a compd. contg. 33 mol. % HCONH_2 ; HCOOH and HCONH_2 do not give a viscosity max., but form an equimol. compd. which is quite stable.

E. B. MILLARD.

Alcoholic solutions of cadmium iodide. F. H. GETMAN AND V. L. GIBBONS. *J. Am. Chem. Soc.* 37, 1990-6(1915).— CdI_2 (dried, but not otherwise purified) was dissolved in MeOH or EtOH , and the cond. of the solns. measured at 25° by the Kohlrausch method in a cell of the "ordinary Arrhenius form." Some of the solns. were made by direct weighing, the others by diluting these solns. The conductance curve for MeOH solns. (13 concns. between 2.0 and 0.0005 M) indicated complex conditions in the soln. The values in EtOH (9 concns. between 2.0 and 0.005 M) were lower than those of Jones and Carroll (*Bull. Carnegie Inst.* 80, 41-73(1907)); moisture in the solns. would have caused higher values. Certain similarities were observed between these curves and those for AgNO_3 (cf. C. A. 8, 3261). Further expts. were made to det. κ at 20.5° for 8 solns. in MeOH and 11 in EtOH . Plotting κ and d. against concn. showed the relationship in each case to be linear. The sp. refraction in MeOH calcd. on the assumption that the soln. vol. of the salt was zero, was nearly const. in the concd. solns., but increased rapidly with diln. in the less concd. solns. The sp. refraction in EtOH showed no constancy whatever.

E. B. MILLARD.

Potential of the rubidium electrode. G. N. LEWIS AND W. L. ARGO. *J. Am. Chem. Soc.* 37, 1983-90(1915); cf. C. A. 5, 238; 6, 1088; 7, 2341.—The method used consisted in detg. first the normal electrode potential of a dil. amalgam of the metal toward an aq. soln. of the ion of the metal, and second, the difference in potential between the amalgam and the metal in a soln. of a salt of the metal in a

mixt. of EtNH_3 and liquid NH_3 . EtNH_3 alone did not dissolve RbI or RbNH_2 . A mixt. of NH_3 and C_6H_6 sepd. into 2 phases when either Rb or RbI was added, and the phase rich in C_6H_6 contained neither metal nor iodide in measurable amt. The cell for measuring the Rb-RbHg_2 potential was similar to that of Lewis and Kraus, except that an arrangement like a Na wire press was added to produce a fresh Rb surface during the measurements. The normal electrode potential of Rb amalgam was measured in the app. previously used on the other alkali metals. From the two values so obtained, Rb , $\text{Rb}^+(\text{1M}) \parallel \text{N.E.}$; $E = 2.1308 + 1.0745 = 3.2053 \text{ v. at } 25^\circ$. Since there appears to be little hope of detg. the Cs potential in the same way (for the metal is more sol. and the iodide less sol. than in the case of Rb for the solvents investigated), the available normal electrode potentials at 25° are, $\text{Li } 3.305$, $\text{Rb } 3.205$, $\text{K } 3.203$, $\text{Na } 2.993$, and the corresponding potentials against H are 3.027 , 2.928 , 2.925 and 2.715 .
E. B. MILLARD.

Indexes of migration of the ions and transport of ammonia in ammoniacal solutions of cupric sulfate. A. RUYCHLER. *Bull. soc. chim. belg.* 28, 227-9(1914).—Electrolysis of 2 approx. 0.25 N ammoniacal CuSO_4 solns. containing 4 NH_3 per Cu and 4-5 NH_3 per Cu , resp., followed by analysis of the cathodic deposit and the intermediate and cathode liquids showed that the indexes of migration of the ions were the same for ammoniacal as for aq. solns. of CuSO_4 ; the migration of each atom of Cu caused the transport of at least 4, and perhaps even 5, mols. NH_3 .
H. S. PAINE.

Coagulation of arsenious sulfide sol by electrolytes. JNANENDRANATH MUKHOPADHYAYA. *J. Am. Chem. Soc.* 37, 2024-31(1915).—The sols were prepared according to the method of Linder and Picton, and contained 32.9 and 3.54 millimols. As_2S_3 per l. Two others were prepared by dilg. No. 1. The time for coagulation by several salts of various types at different concns. was detd. With diln. of sols of As_2S_3 the stability increases. Fine sols are less stable than coarse ones of the same As_2S_3 content. Coagulation of colloidal As_2S_3 by electrolytes is mainly a coalition of the particles; this takes place all through the substance of the sol with formations of definite clot-like structures. Sedimentation plays an extremely minor part. The rate of coalition is detd. by the concn. and nature of the electrolyte. With concd. sols and relatively dil. electrolytes the coagulation proceeds in stages. Dissolved H_2S stabilizes As_2S_3 against electrolytes to a marked extent. Adsorption of electrolytes does not take place to any considerable extent, as was shown from cond. expts. The order of relative coagulative power of the electrolytes for As_2S_3 was $\text{Al}_2(\text{SO}_4)_3$, $\text{Ba}(\text{ClO}_3)_2$, BaCl_2 , SrCl_2 , MgSO_4 , HCl , NH_4Cl , KCl , KNO_3 , KBr , NaCl , KI , NaNO_3 , LiCl . E. B. M.

Dilution law at higher concentrations. C. A. KRAUS. *Z. Elektrochem.* 20, 524-9(1914).—A claim of priority over Sakhanov and Prsheborovskii (*C. A.* 8, 1371) and a criticism of the use made by Sakhanov (*Z. physik. Chem.* 88, 144(1913)) of the viscosity detns. of Sprung (*Ann. Phys. Chem.* [ii] 159, 1(1876)) in correcting elec. cond. detns. for the influence of viscosity. See also Kraus and Bray, *C. A.* 8, 854. E. B. M.

Equilibrium between carbon oxydisulfide, carbon monoxide and sulfur. G. N. LEWIS AND W. N. LACHY. *J. Am. Chem. Soc.* 37, 1976-83(1915).—In order to calc. the free energy of formation of SO_2 from its reduction to S by CO , the free energy of formation of the intermediate product is required, according to the reaction $\text{CO} + \text{S} = \text{COS}$. About 100 cc. of CO was heated with an excess of S in an app. wholly of glass at 302° in a bath of boiling Ph_2NH . The bath liquid carbonized somewhat on long boiling, but this seemed to have no effect on the temp. of the vapor. COS was absorbed in alkali and titrated with I after adding HCl . The uncombined CO (about 1% of the original gas) was detd. by solidifying the COS with liquid air and drawing off the uncondensed gas. This gas was found to contain some CS as well, and this CS was removed by passing the gas over a Pt wire plated with Cu and electrically heated to

dull redness. $K = [\text{COS}]/[\text{CO}] = 201$. If $S_{\lambda\mu}$ represents liquid S in equil., $S_{\lambda\mu} + \text{CO(g)} = \text{COS(g)}$; $\Delta F_{171} = -6070$ cal., and for $S_R + \text{CO(g)} = \text{COS(g)}$; $\Delta F_{171} = -6410$ cal. Other expts. at 260° gave as a preliminary value $K_{171} = 435$. The presence of CS , CO_2 and CS_2 was mentioned.

E. B. MILLARD.

Equilibrium in the system: hydrogen ion-alcohol-water. H. GOLDSCHMIDT. *Z. Elektrochem.* 20, 473-9(1914).—If the elec. cond. of a soln. of an acid in aq.-alc. is known for 3 different H_2O concns., the value of the equil. const. of the system $\text{H}^+ - \text{H}_2\text{O} - \text{EtOH}$ can be calcd. Expts. are given which include equivalent conductivities at 0.1 N and Δ_0 for HCl , 5-sulfosalicylic, picric, CCl_3COOH , trinitrobenzoic, trichlorobutyric, dichloroacetic, and salicylic acids. The equil. const. for alc. with varying % of H_2O has been calcd. from the conds. taken.

Changes of phase under pressure. II. New melting curves, with a general thermodynamic discussion of melting. P. W. BRIDGMAN. *Phys. Rev.* 6, 94-112(1915); cf. *C. A.* 8, 2295; 9, 2479.—The conclusion of a previous paper is confirmed, namely, that unless there is a reversal at high pressures of the effects found up to 12000 kg., the m. p. curve continues to rise with pressure and temp. indefinitely, with neither a maximum nor a critical point. The equation of the melting curve has been obtained in terms of the difference of compressibility, thermal expansion and sp. ht. between the solid and the liquid. On account of certain exptl. inequalities an approx. value of the difference of compressibility between solid and liquid may be obtained by assuming that the difference of sp. ht. is zero. The liquid and solid approach each other more rapidly in compressibility than they do in vol. A suggestion as to the mechanism of melting is found in the fact that the equation of the melting curve involves the properties of both liquid and solid.

E. B. MILLARD.

Kinetics of the bromate-nitrite reaction. A. KURTENACKER. *Monatsh.* 36, 451-6(1915).—The HOAc concns. of *Monatsh.* 35, 925(1914) (cf. *C. A.* 9, 744) should be decreased 4%, on account of an error in calcn. of the first results. In this series of expts. the influence of pressure on the velocity of reaction of KBrO_3 and KNO_2 (in the presence of HOAc) has been investigated. Decreasing the pressure to about 40 mm. decreased the speed of the reaction 15%, indicating that the bromate was reduced by NO and not by HNO_2 , since pressure could have no effect on the concn. of the latter substance. Another factor must be considered, since the vacuum caused an increase in the speed of formation of NO from HNO_2 , thus increasing the speed of bromate reduction. The "true speed of the reaction" was calcd., after taking the NO into account. Further expts. at 20, 30, 40 and 50° were made, and the results discussed in the light of the Arrhenius equation in the integrated form, $\log(K_1/K_2) = A(T_1 - T_2)/T_1T_2$. Values of A decreased with increasing temp. in place of remaining const. as required by the equation.

E. B. MILLARD.

Catalyses with weak acids. VI. Rate of conversion of cinchonine into cinchotoxine. H. C. BIDDLE AND O. L. BRAUER. *J. Am. Chem. Soc.* 37, 2065-82(1915); cf. *C. A.* 7, 3872.—Using the polarimetric method, detns. were made of the rate of conversion of 0.1 M cinchonine (a) at $99.7^\circ \pm 0.2^\circ$ in 0.15-8.0 M AcOH , 0.2-0.8 M HCO_2H , 0.2-0.8 M EtCO_2H , 0.2-0.3 M $(\text{CO}_2\text{H})_2$, 0.15-0.175 M HCl , 0.1-0.21 M $\text{HCl} + 1.0 M$ AcOH , of 0.25 M (a) in 0.50-2.50 M AcOH and of 0.01 M (a) in 0.05-0.80 M AcOH . In the AcOH expts. the values of the sp. reaction velocity, K_1 , are arranged in order of increasing AcOH concn. in 3 tables; in the 1st, the AcOH concn. is expressed in terms of the total AcOH added, in the 2nd in terms of the AcOH in excess of that necessary for the formation of a monoacetate, and in the 3rd in terms of the AcOH in excess of that required for the formation of a diacetate. Exam. of these tables leads unavoidably to the conclusion that the rate of reaction is more correctly represented as a function of the acid concn. in excess of that required for the formation of the mono-

acetate; in the 2nd table, where the reaction is assumed to be monomol. with respect to (a) monoacetate and the AcOH in excess of that required for the formation of this salt is regarded as expressing the concn. of the catalyzer, the values for K_1 increase in general with increasing concn. of the AcOH, and these increasing values correspond with fair uniformity for the 3 different concns. of (a) studied. The expression K_2/acid , representing the relation between the speed of the reaction and the concn. of the acid in excess of that required for the formation of the monoacetate, gradually decreases with increasing concn. of the acid. The expts. with other acids showed that the rate of reaction decreases with increasing dissociation consts. of the acids; with EtCO_2H , AcOH and HCO_2H , the speed of conversion increases with increasing concn. of acid; with HCl and $(\text{CO}_2\text{H})_2$, the reverse is true. With the 1st three, the rate of increase in speed with equal increments in concn. is greatest with the acid of lowest and least with the acid of highest dissociation const. In the AcOH + HCl expts. it was found that, keeping the AcOH concn. const. (1.0 M), the value for K_2 fell from 0.0566 for 0.0 M HCl to 0.00 for 0.3 M HCl, while keeping the HCl concn. const. and increasing that of the AcOH produced an increase in the speed of reaction of the monoacetate, mono- and di-hydrochlorides of (a); for any given concn. of AcOH, the speed is greatest for the 1st and least for the 3rd salt. Moreover, the ratios between the speeds for different salts with equal concns. of org. acid seem to approach a const. value, the ratio *speed mono-HCl salt; speed di-HCl salt* being 11.5, 11.5, 12.7, 11.3 in 0.1, 0.2, 0.4 and 0.8 M AcOH, resp. B. and B. conclude that the function of the org. acid is that of a true catalytic agent, accelerating but not causing the reaction. The effect of H ions is to inhibit the reaction. As shown below, the rate of reaction is a linear function of the concn. of undissociated org. acid. VII. Rate of conversion of cinchonidine into cinchotoxine. H. C. BIDDLE AND R. H. BUTZBACH. *Ibid* 2082-7.—Expts. with cinchonidine (b) like those carried out with (a) (above) gave entirely analogous results. Comparison of the values obtained in equal concns. of acid shows that in general (a) reacts slightly (about 1.21 times) more rapidly than (b). VIII. Nature of the catalysis in the conversion of the cinchona alkaloids into their toxines. H. C. BIDDLE. *Ibid* 2088-112.—Assuming that in an aq. soln. containing cinchonine (a), HCl and an org. acid there is no undissociated (a) salt or HCl, the H ion concn. can be calcd. (see original for formulas) in terms of the dissociation const. k_3 of the org. acid, the 1st and 2nd dissociation const., k_1 and k_2 , of (a), and the ionization const., k_w , of H_2O . k_w at 100° was taken as 48×10^{-14} (Noyes, C. A. 2, 614), k_3 as 1.11×10^{-8} for AcOH (N., C. A. 4, 854) and 1.31×10^{-4} and 0.86×10^{-8} for HCO_2H and EtCO_2H , resp. (calcd. on the assumption that the values of k_3 for the 3 acids bear the same relation to each other at 100° that they do at 18°). By a method not yet published, k_2 was found to be 1.11×10^{-9} ; k_1 may be neglected. Knowing the H ion concn., that of the undissociated org. acid and of the uni- and bivalent (a) ions can readily be calcd. Applying these calcns. to the expts. reported above, it is found that the graph obtained by plotting the sp. reaction rates against the concn. of H ion, for solns. of const. concn. with respect to the undissociated org. acid, is a regular curve in which the sp. reaction rates change the more rapidly the lower the concn. of the H ion. The sp. reaction rate at const. concn. of the catalyzing acid in solns. of const. concn. with respect to the alkaloid is directly proportional to the concn. of the univalent (a) or (b) ion. The sp. reaction rate at const. concn. of the univalent (a) or (b) ion is a linear function of the concn. of the undissociated org. acid, showing that an undissociated mol. (in this case an electrolyte) in homogeneous soln. can act as a direct catalytic agent through a wide range of concn. The abs. reaction rate for org. acids appears to be directly proportional to the mol. wt. of the acid, as found with HCO_2H , AcOH and EtCO_2H ; this relationship, however, is probably accidental. The sp. reaction rate, which, under like conditions, should theoretically be independent of the initial concn. of the (a) or (b), increases slowly

with increasing concn. of the alkaloid, a phenomenon similar to that encountered in the inversion of cane sugar and the hydrolysis of esters. The const. difference (1.21:1) in the rate of sp. reaction of (a) and (b) under like conditions is apparently to be attributed solely to the stereoisomeric difference existing between the 2 alkaloids. A tentative suggestion as to the mechanism of the reaction involved in the conversion of the tertiary cinchona alkaloids into their toxins containing a secondary N atom, a reaction shown to be catalyzed by org. acids, is that a cinchotoxine acyl deriv. is formed as an intermediate product, a hypothesis strengthened by the ease with which the alkyl halides of the alkaloids are converted into toxins and by the influence exercised by the concn. of the AcOH in the conversion of PhNH_2 into PhNHAc . The mathematical proof of the reaction given in this paper does not necessarily exclude the possibility that partially ionized cinchonine salt may take some part in the reaction. Furthermore, no account has been taken of the role played by the undissociated salt, which is undoubtedly present. These factors will doubtless largely explain the deviations in the reaction rate occasioned by varying initial concn. of the alkaloid. These and other factors will be taken up in a subsequent paper.

CHAS. A. ROULLER.

Melting point of tungsten. IRVING LANGMUIR. *Phys. Rev.* 6, 138-57(1915).—Observations on evacuated and on gas-filled W lamps indicate that the intrinsic brilliancy of solid W at a temp. just below the m. p. is about 7200 international candles per sq. cm., which, according to the Rasch equation, should correspond to 3540°K . for the m. p. This m. p. has also been detd. by means of a Holborn-Kurlbaum pyrometer as 3532°K ., corresponding to an emissivity of 0.46 for $\lambda 0.667 \mu$; and from the brilliancy of the molten surface of an a. c. W arc in an atom of N as 3566°K ., corresponding to an emissivity of 0.425 for $\lambda = 0.667 \mu$. The most probable value is $3540^\circ \pm 30^\circ \text{K}$.

E. B. MILLARD.

Researches on ammonia. IV. Determination of the heat of formation of ammonia at high temperatures. F. HABER AND S. TAMARU. Kaiser Wil. Inst. *Z. Elektrochem.* 21, 191-206(1915); cf. *C. A.* 9, 1423, 2013.—A continuous flow method was used. NH_3 gas was decomposed, with the aid of granular Fe as catalyzer, within an elec. furnace, and the heat required was supplied electrically in a form convenient to measure. The possible sources of error are very elaborately discussed. The "decomposer" was so poorly insulated thermally from the copper vessel in which it was contained that when the gas stream was at rest the temp. of this vessel was said to be given more accurately by the temp. of the decomposer than by a thermoelement inserted in the wall of the vessel. Nevertheless, by means of observations on non-decomposing gases the authors estimate that they have reduced the uncertainty from this cause to 2 per mille or less in the final result. A lack of uniformity in the temp. of the decomposer produces a further uncertainty which is estd. as not over 0.5%. Yet another uncertainty comes from decompn. in other parts of the hot app. than in the decomposer. By taking out the decomposer and running through gases of different compn. upper and lower limits of the error from this cause were found, ranging from 3 to 10% at 554° and higher. At 503° and 466° there was very little decompn. except in the decomposer. No estimate of the final accuracy appears to have been made, but the results of different groups of observations nearly always agree to 2% below 500° , and to 4% above that. The results are: For atmospheric pressure, heat of decompn. per mol. at 659° , 13000 cal.; the mean value in the range of temp. $466-554^\circ$ is 12700 cal. **V. Heat of formation of ammonia at ordinary temperatures.** F. HABER, S. TAMARU AND L. W. ORHOLM. *Ibid* 206-228.—Using the continuous flow method NH_3 was decompd. by heat with the catalytic aid of Fe and Os within a vacuum-jacketed vessel containing water. In the electrically heated decomposer the temp. probably reached a red heat, but the in-going and out-coming gas was near

room temp. For reasons not given the authors chose to put in an excess of heat, removing it by a stream of water, flowing through a fine coiled pipe. The errors are carefully discussed; chief among these was that in measuring the elec. energy. The heat of decomp. per mol. is believed to lie between 10950 and 11000 cal. This is 8 to 10% below results of Thomsen and Berthelot, a difference not surprising in view of the possible errors of their methods. VI. The specific heat of ammonia. F. HABER AND S. TAMARU. *Ibid* 228-241.—The sp. heat was detd. by heating the gas electrically as it ran through a heated vessel. Errors due to conduction within the vessel, and other systematic errors, were learned by detg. the sp. known heats of other gases. The method thus amounts to calibrating the app. empirically by means of other gases, detd. by other investigators. As far as the accidental errors go, the results agree to 1%, and are not given closer. The results are: At 309°, 10.3; at 422°, 11.0; at 523°, 11.8. These results are found to be not inconsistent with the quantum theory. VII. The action of uranium as catalyzer in the synthesis of ammonia from its elements. F. HABER AND F. C. GREENWOOD. *Ibid* 241-5.—Uranium carbide was made in an arc furnace from the oxide and an excess of resin lampblack. This compd. caused the formation of NH_3 under pressure at about 500°. The active agent was found to be a compd. of the probable compn. U_2N_4 , which forms gradually from the carbide as the gas flows. In presence of O or H_2O the mass becomes compacted and less effective, owing probably to the cementing action of the oxide. Admixture of graphite diminishes this action, but also diminishes the catalytic action. Metallic uranium made in several different ways (in all cases containing some oxide) also gave catalytic action, but less effectively than the carbide. A body of catalyzer of given size works most effectively in a rapid stream of gas and at high pressure, though the proportion of gas changed is less than in a slower stream. Practically, since the active compd. must be small in dimensions on account of the high pressure and rather high temp. desirable, the rate of working for a given sized body is the more important thing. The equil. constant near 537°, that is, the ratio of the partial pressure of NH_3 to the product of (p. p. of N)^{1/2} and (p. p. of H)^{3/2} was found to be from 24.6×10^{-4} to 28.7×10^{-4} . A lecture app. for demonstrating the direct union of N and H is described.

S. LEVY.

Electrons and heat. O. W. RICHARDSON. King's College, London. *Engineering* 99, 631-2(1915).—This is the report of a lecture on "Electrical Evaporation," dealing with the liberation of positive ions and electrons from bodies by the action of heat. The following facts, though not new, are conveniently brought together: (1) Positive ions are given out at dull red heat from metals and negative electrons in increasing ratio at higher temps. (2) The amt. of electron evapn. from W followed an ordinary vapor tension formula of fluids through a temp. interval where the amt. of evapn. increased 300 billion times. (3) The elec. evapn. consumes heat, shown, with closely concordant results, in 3 different ways. (4) The velocities of the escaping electrons obey Maxwell's distribution law. In fact, their measurement was the first exptl. verification of that law ever made. It was effected by finding the varying number of electrons that were able to travel a given distance against different opposed voltages. Evidence was also given that elec. evapn. is not a chem. phenomenon, but this part of the report appears to be a little confused.

W. P. WHITE.

Thermoelectric properties of carbon. W. C. MOORE. *J. Am. Chem. Soc.* 37, 2032-7 (1915).—Five pieces of C were clamped in turn against a single specimen; leads were fastened to the free ends, and the circuit was completed through a millivoltmeter used as a galvanometer. The clamped ends were heated, and in every case except the one in which the 2 pieces of C were of the same material, a considerable e. m. f. was developed. Expts. were also made on C-Cu junctions in a C tube from which air was removed. The study of the thermoelectric properties offers evidence that amorphous C is not a single definite substance. The properties vary with temp., and are detd. by the kind of raw material used and the manufacturing history of the specimen. The fact that with some varieties of arc carbons a considerable temp. range of const. e. m. f. was found indicates the possibility of a transition interval of these carbons.

E. B. MILLARD.

Photo-electric phenomenon exhibited by liquid dielectrics. L. STRAMP. Louvain. *Bull. soc. acad. roy. belg.* 1914, 45-62.—S. has shown that ultraviolet rays influence the elec. discharge of liquid paraffin, petroleum, shale oil and Russian mineral oil; this discharge is more rapid for a positive charge in the case of the 2 former and for a negative charge in the case of the 2 latter. This effect is due to a photo-elec. surface phenomenon and it is shown that it cannot be caused by ionization of the air or by a vol. phenomenon.

H. S. PAINE.

Number of atoms involved in the emission of spectrum lines. R. LADENBURG. *Verh. deut. physik. Ges.* 16, 765-79 (1914).—Theoretical. The value of the ratio $H/\mathfrak{M}$ has been shown by several independent methods to be a universal constant. If an electron is the oscillator, the ratio is $C = 8\pi^2 e^2 / mc = 0.67 (\text{cm}^2/\text{sec.})$. The ratio is that of the energy H of an oscillator of vibration frequency ν to the specific intensity $\mathfrak{M}$, of a "Hohlraum" of the same temp. and vibration number. From Gouy's measurements on Na flames it appears in the light of these calcns. that from 100 Na atoms there are emitted 40 electrons which are concerned with the D-line. E. B. MILLARD.

Experimental verification of the Lorentz-Einstein formula for cathode rays of high velocity. C. E. GUYE AND C. LAVANCHY. *Compt. rend.* 161, 52-5 (1915).

E. B. MILLARD.

Index of refraction of gases. J. T. HOWELL. *Phys. Rev.* 6, 81-93 (1915).—Expts. have been made on O_2 (98 to 99%), H_2 (99.8%) and CO_2 (commercial grade, not tested for purity) by means of interferometer plates nicked by cathode discharge, a Fabry and Perot interferometer, and a quartz spectrograph, extending the dispersion curve to $\lambda 2753$ for these gases and to $\lambda 2652$ for air. Over the region previously investigated the curves agreed well with those of other observers. The ratio of the charge of an electron to the charge of an ion, as calcd. from the H curve, was 0.94.

E. B. MILLARD.

New experiments in the ultra-red spectrum. W. H. WESTPHAL. *Die Naturwissenschaften* 2, 621-6 (1914); *Chem. Zentr.* 1914, II, 858.—Review of the most important work in the extreme red spectral range during the last year. The review treats of short-wave and long-wave ultra-red, emission and absorption spectra, interferometric measurements of wave length in the long-wave ultra-red, generation of long ultra-red radiation over any desired range of wave length by methods of selective dispersion, absorption, reflection or emission, and the analogies between long-wave ultra-red radiation and elec. waves.

E. B. MILLARD.

Resistance measurements and optical measurements on thin platinum films. BELA POGÁNY. *Physik. Z.* 15, 688-90 (1914); *Chem. Zentr.* 1914, II, 563; cf. Planck, *C. A.* 8, 2841.—P. has detd. the sp. resistance of very thin Pt films and found that below $7\mu\mu$ this resistance increases very greatly. The films were prepd. by cathodic

disintegration; the thickness was detd. by means of a chem. microbalance. This change in elec. conductivity shows itself in the optical behavior of the films (* and absorption index), the change in these quantities with the thickness following essentially the theory developed by Planck. E. B. MILLARD.

Application of the quantum theory to the ultra-red absorption spectrum of water vapor. A. EUCKEN. *Verh. deut. physik. Ges.* 15, 1159-62(1913).—From the assumption that energy radiation is discontinuous, E. has calcd. the positions of lines in 2 series of the ultra-red absorption spectrum of H₂O vapor. The agreement with observed values was satisfactory enough to show the correctness of the discontinuity assumption, rather than some other assumption. Cf. Planck, *C. A.* 5, 1697. E. B. MILLARD.

Comparison of wave length of the neon line (λ 6402) with that of the cadmium line (λ 6438) by the method of coincidence of interference points. TOSHIO TAKAMINE. *Proc. Tokyo Math.-Phys. Soc.* [2] 8, 9-12(1915).— λ'_m (mean of λ') = 6402.2395 $\pm$ 0.00009 for the neon line, which confirms the results of Priest (*C. A.* 7, 1323) by a different method. W. H. FRY.

The structure of some spectrum lines of bismuth and cadmium. TOSHIO TAKAMINE. *Proc. Tokyo Math.-Phys. Soc.* [2] 8, 51-8(1915).—Lines λ 5086, λ 4800, λ 4678, Å. of Cd were examined by an echelon crossed with a Lummer-Gehrcke plate and positions of satellites found to agree with the results of previous investigators. Lines λ 6438, λ 5155, λ 4663 Å. always appeared simple. Bi λ 4722 was found to have 5 satellites and Bi λ 4122 was resolved into 4 components. λ differences and relative intensities are given. W. H. FRY.

Optical rotatory power of derivatives of succinic acid in aqueous solutions of inorganic salts. II. G. W. CLOUGH. *J. Chem. Soc.* 107, 96-104(1915); *Proc.* 30, 307-8; cf. *C. A.* 8, 1569.—The rotatory powers of Me H *d*-tartrate and Na H *d*-tartrate have been detd. at various temps. in H₂O and in aq. solns. of NaCl. Me H tartrate is dextrorotatory in aq. soln.; the sp. rotation is increased by dilution or by rise of temp., but is decreased by the presence of NaCl. This ester resembles tartaric acid and the neutral Me ester in this behavior and in that it exhibits levorotation in a concd. soln. of BaBr₂. The curves for Me H tartrate bear considerable resemblance to those for tartaric acid. Na H tartrate has been studied in H₂O and in NaCl solns. at various temps. for 3 wave lengths: Hg-green, Hg-yellow and Na-yellow. The sp. rotation is almost independent of concn. and the influence of temp. is the same for all solns. The sp. rotatory power attains a max. value which is const. from 40° to 70°; it is depressed by the presence of NaCl, but the relative depression is much less than that produced by NaCl on tartaric acid or its esters. The optical rotatory dispersive ratios appear to be practically independent of the temp. and concn. for solns. of Na H tartrate. The behavior of the Na or K neutral tartrates toward NaCl or KCl is in striking contrast to that of the acid, the esters or acid salts, and it has even been shown that NaCl decreases the rotation of di-Na tartrate while KCl increases the rotation of di-K tartrate. Na salts decrease, and K salts increase, the rotation of Na K tartrate. Na and Ba halides (and probably most inorganic salts) in aq. soln. exert a specific effect on hydroxy derivs. of succinic acid contg. —CO— or carbalkyloxy groups, the effect being usually opposite to that caused by dilution. Work on amino derivs. is in progress. E. B. MILLARD.

Extinction of ultraviolet light in the earth's atmosphere. E. KRON. *Ann. Physik* 45, 377-98(1915).—Discussion of the numerous measurements of the limits of ultraviolet solar radiation recorded at various zenith distances to det. the degree of extinction of ultraviolet radiation by the atm. The limit of effective rays is near λ 3250. E. B. MILLARD.

Metamagnetic alloys. KURT OVERBECK. *Ann. Physik* 46, 677-97(1915).—

Most specimens of Cu-Zn alloys show diamagnetic properties which are normal in increasing field strengths. Some alloys were found, however, which showed an initial weak paramagnetism; the paramagnetism becomes weaker with increasing field strength, and finally becomes diamagnetism. Expts. have been made on alloys starting with pure Cu and going gradually to pure Zn, in field strengths up to 12000 gauss. The behavior of the alloys suggests that of Fe, where the susceptibility depends to a certain extent on field strength, and to study this similarity, expts. were made with Cu-Fe, Zn-Fe, and brass to which borax, Al, Al and Fe, and Fe alone had been added. This change from para- to diamagnetism (called metamagnetism) was not found in the brass-Al alloy, but was produced artificially in brass by the addition of 0.0233% Fe. Metamagnetism was indirectly shown to be due to the presence of traces of Fe, and was not found in the alloys contg. no Fe.

Advances in the field of radioactivity in 1913 and 1914. F. HENRICH. *Z. angew. Chem.* 28, I, 297-303, 305-8, 313-5(1915).—A thorough review with bibliographic references.

E. J. C.

The photographic action of alpha, beta and gamma rays. R. R. SAHNI. Manchester. *Phil. Mag.* 29, 836-41(1915).—Photomicrographs are reproduced showing the effect on a sensitive Wratten and Wainwright's lantern plate of the rays from Th active deposit, Po and Ra C deposited on the tips of fine needles touching the plate. Alpha rays show straight tracks radiating from the needle tip and forming a circular nucleus on longer exposure. An occasional track is bent as the result of "scattering." The tracks from Th active deposit are noticeably longer than those from Po. The β - and γ -rays give no straight tracks or radial traces. Their impressions are scattered and the nucleus is irregular.

G. L. WENDT.

Ionization by positive rays. NORMAN CAMPBELL. Leeds. *Phil. Mag.* 29, 783-94(1915).—When positive rays from a layer of heated phosphate are allowed to fall on a polished Cu plate the number of electrons emitted by the plate increases rapidly with the potential through which the positive particles fall, up to 10,000 v., then more slowly, with a max. at 38,000 and a rapid decline thereafter. In analogy with a similar effect for cathode rays at 11 v., it is suggested that at 38,000 v. the positive rays begin to resemble α -rays and are able to penetrate the atoms. Somewhere below 100,000 v. they should acquire the great ionizing power of α -rays and the electron emission should increase.

4. ELECTROCHEMISTRY.

COLIN G. FINK.

Electric furnace melting of ferro alloys. R. S. WILE. *Trans. Am. Electrochem. Soc.* 28 (advance copy) (1915).—A resistance furnace of the 3-phase type, 1 bottom and 2 top electrodes, is described (without fig. or photo). The spacing of the electrodes is such that they compose an equilateral triangle. To start, the 2 top electrodes are lowered to the floor of the furnace, some granular graphite is sprinkled in and

when this glows the slag-making materials are added. After melting the slag, the top electrodes are raised slightly. The alloy is then charged into the furnace and is melted beneath the slag, the heat being regulated by the depth of the electrodes in the slag. Extensive tests were carried out to prove that there is no change in the alloy while melting. The following conclusions are based on an 80% ferro-manganese: The av. power consumption is nearly 800-kw. hrs. per ton. The C electrode consumption is never over 12 lbs. per ton. Lining cost is 10 and 25 cts. per ton depending upon the rapidity of melting. Besides, there is a considerable saving in Mn as compared with other processes. In the case of ferro-Cr the total saving is even greater than in the case of ferro-Mn. The Wile furnace has also been tried out successfully in the smelting of Bolivian Sn ores and concentrates. An acid slag was used with a loss of only 1.89% Sn or 0.5% of the Sn content. The product ran 98.75% Sn as compared with 95% and 96% by older methods. The power consumption was less than 450 kw.-hrs. per ton of concentrates. Analysis of concentrates: Sn 66.96, SiO₂ 5.24, Fe 0.92, S 1.14%.

C. G. F.

Solution stratification as an aid in the purification of electrolytes. FRANCIS R. PYNE. *Trans. Am. Electrochem. Soc.* 28 (advance copy) (1915).—In the electrolytic refining of Cu the tendency of the electrolyte to stratify or form layers of various compn. is one of the attendant evils. To overcome this P. and Green have invented a new tank (U. S. pat. No. 1,148,798; cf. *C. A.* 9, 2488). In the old method the tank

house electrolyte first passed through tanks containing insol. anodes to remove a portion of the Cu; requiring high power consumption and giving a product of inferior quality; thence to a second set of insol. anode tanks to remove the remainder of

the Cu and some of the impurities, after which the soln. was treated in any desired manner. In the present method, the tank house electrolyte is drawn directly from the new stratification tanks, requiring no increase in power and avoiding the production of inferior grades of product; thence to the final insol. anode tanks, as above. In the Fig. is shown a sectional elevation of the tank. 'AB' is the slime line, H the outlet for removal of slime from the tank, and CD the soln. line. After proper regulation has been made the regular tank room soln. enters at E; a soln. high in Cu is withdrawn through F while the soln. from G is low in Cu and passes directly to the final insol. anode tanks. A uniform deposit on the cathode is obtained. The net saving is the operation of one set of insol. anode tanks.

C. G. F.

Overhead electrolysis and porcelain strain insulators. S. L. FOSTER. *Proc. Am. Inst. Elec. Eng.* 34, 1549-58 (1915).—Conditions of atm. electrolysis in San Francisco and the remedies applied are given. There is a slight leakage from trolley wires to earth through the insulated supports on all overhead construction. If not checked this results in electrolysis of H₂O and the rapid corrosion of any adjacent metal parts. This electrolytic effect may also take place over strain insulators where the creepage distance is not great enough. The electrolytic action removes first the galvanizing upon the surface and then rapidly attacks the Fe. This is prevented by painting or oiling all galvanized wires and supports which are alive. Another form of electrolysis met with in overhead work is due to the use of dissimilar metals in contact. In this case, H₂SO₄ and other fumes in the air or O₂ is supposed to form the electrolyte. It was found that porcelain insulators gave the best all-round results under the conditions of fog and rain met with locally. Under severe conditions a creepage distance of 2" did not prevent the rapid corrosion of the galvanized support cables.

W. E. RUDER.

Experimental researches on skin effect in conductors. A. E. KENNELLY, F. A.

LAWES AND P. H. PIERCE. *Proc. Am. Inst. Elec. Eng.* 34, 1749-1818(1915).—After a brief historical sketch and a description of the app. employed, the authors give the results of about 100 series of tests each covering a range of frequency up to 5000 cycles per sec. These tests were made on round, rectangular solid and stranded Cu and Al cables and tubular conductors. The skin-effect impedance-ratios of solid round wires of Cu or Al were found to be in close agreement with the Bessel-function Heaviside-Kelvin theory up to the frequency limit of tests made. Below 100 cycles the *proximity* effect is relatively small. Stranded Cu or Al conductors without twists have the same skin-effect impedance-ratio as their equi-sectional solid conductors. Twisting or spiraling causes a slight increase in skin-effect. Cu strips have a much larger skin-effect resistance-ratio than corresponds to the theory for indefinitely wide strips. Cu tubes have a lower skin-effect than any other form of equal section. Half tubes have a much greater skin-effect than whole tubes. The theory of skin-effect in solid cylindrical uniform conductors with remote return is fully discussed and a complete bibliography of the subject is appended.

LOUIS DERR.

Retarding action of sugar on development and permeability of gelatin to developer containing sugar. J. MALDINEY. *Compt. rend.* 161, 73-6(1915).—A normal metol-hydroquinone bath, functioning regularly in 5 sec. on bromide paper, was found capable of retardation 3-5 min. by addition of sugar. To test whether the retardation was due to increased viscosity, the lower edges of strips of plate were dipped in developing solns. containing varying proportions of sugar, and the rate of imbibition measured

by the rise of the liquid into the gelatin. Observation was facilitated by adding a trace of phenolphthalein to the emulsion, which produced a red tint in the absorbed liquid. The rate of penetration decreased with increasing conc. of sugar, from which it appears that the retardation of development is largely a matter of viscosity.

L. DERR.

Comparative studies on color rendering of photographic gelatin plates. III. E. STENGER. *Z. Reproduktionstechnik* 17, 2-4, 22-4, 31-3, 38-41, 46-9, 54-7(1915); cf. *C. A.* 9, 31, 180, 564.—Spectroscopic studies of plate sensitiveness, largely in the form of curves and tables which cannot usefully be given in abstract. Pinachrome violet is slightly better in conferring red-sensitiveness than pinacyanol, but is much the same otherwise; in association with pinaverdol, orthochrome and pinachrome, the best mixture is that with orthochrome, the bath being: alc. 100 cc., water 200 cc., 1% pinachrome violet 3 cc., 1% orthochrome 3 cc. The plates are bathed 3 min., and dried in total darkness. Compared with similar pinacyanol mixtures, pinachrome violet shows no superiority. A new isocyanine, *m*-toluquinolinequinaldine diethylisocyanine iodide, even in best conc., is far inferior to ethyl red, and its usefulness seems limited, as emulsion-dyed plates show much less color sensitiveness than bathed plates.

L. DERR.

6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

New crystalline variety of silver. T. C. CHOUDHRI. *J. Am. Chem. Soc.* 37, 2037-9(1915).—Spongy Ag, prepd. by igniting Ag tartrate, was treated at ordinary temps. with HNO_3 (1.42) from which lower oxides of N had been removed by boiling with carbamide. At first some action took place, but after a time the soln. of Ag stopped, and on allowing the mixt. to stand with occasional shaking for 2 weeks, the remaining Ag was converted into long needle-shaped crystals easily visible to the naked eye; slender needles which are at first formed appear floating on the surface of the acid liquid. As the conversion into a cryst. variety takes place at ordinary temps. in a heterogeneous system, Smit's dynamic theory of allotropy does not apply.

E. B. MILLARD.

Sodium silicates. ALFR. ERDENBRECHER. *Chem. Ztg.* 39, 583(1915).—E. has isolated a new hydrate, $\text{Na}_2\text{SiO}_3 \cdot 4\text{H}_2\text{O}$, m. 89.2° . Cf. *C. A.* 8, 3539. J. H. M.

The ferrocyanides of bivalent and trivalent vanadium. G. LEVI. *Atti accad. Padova* 31, 1(1915).—Reduction by electrolysis is unsatisfactory in obtaining trivalent V, but $\text{Na}_2\text{S}_2\text{O}_4$ will reduce penta- or tetravalent V to the trivalent stage without carrying the reduction to the divalent stage, even if present in excess. The acid soln. of tetravalent V is treated with an excess of $\text{Na}_2\text{S}_2\text{O}_4$, boiled for a few min. in an atm. of CO_2 and pptd. (at $30-40^\circ$) with the calc. amt. of $\text{K}_4\text{Fe}(\text{CN})_6$. The ppt. is rapidly filtered and washed in an atm. of CO_2 , then decomposed with concd. H_2SO_4 and the residue fused with Na_2CO_3 and KNO_3 . The Fe is detd. as Fe_2O_3 and the V as V_2O_5 . Detns. of Fe/V gave 0.832, 0.840, 0.829 (theor. = 0.821). $\text{V}_4[\text{Fe}(\text{CN})_6]_3$ loses C_2N_2 on drying, oxidizes on exposure to air and is insol. in acids except concd. H_2SO_4 . $\text{V}_3\text{Fe}(\text{CN})_6$ (?) is prepared by the electrolysis of an acid soln. of tetravalent V and pptn. as above. The brown ppt. is insol. in acids except concd. H_2SO_4 and resembles $\text{V}_4[\text{Fe}(\text{CN})_6]_3$ in most respects.

L. T. FAIRHALL.

The action of nitric acid on aluminium. A. TRILLAT. *Bull. soc. encour. ind. nat.* 122, 547-54(1915).—The character of the action varies with the purity of the Al, the nature of the impurity, the conc. and purity of the HNO_3 , the temp. and the absence

or presence of air. T. in his expts. used acid of 3 concs., (1) 99.7%, (2) 63.3%, (3) 21.6% HNO_3 . The Al, 99.7% pure, was cut in bars $100 \times 28 \times 1$ mm., one side of which was polished, the other rough. Immersed in acid (1) at 0° for 15 days in the absence of air, the loss in wt. was 0.54%, at 28° , 4.3%. In acid (2) at 8° the loss was 8.8%, at 28° 31.1%. In acid (3) at 18° the loss was 11.8% and at 28° 46.1%. The bars immersed in the conc. acid preserved their initial appearance while those in the dil. solns. became more or less encrusted. In the presence of air corrosion was more marked. The presence of Cu, Na, Mg, Cl, and HCl accelerated the attack.

H. L. OLIN.

Catalysis of hydrogen peroxide (decomposition) by acids and alkalis in a homogeneous medium. GEORGES LEMOINE. *Compt. rend.* 161, 47-51(1915); cf. C. A. 9, 401.—The expts. were on 3% H_2O_2 at 65° in the presence of HCl and H_2SO_4 , following the discovery (1912) that H_2O itself could catalyze the decompn. if it was present in sufficient excess. Decompn. was slower in the presence of increasing quantities of acid, but the retardation was not proportional to the acid concn. This retardation was explained on the assumption that the acids had great affinity for H_2O , and that they therefore removed the "water," as such, from soln., thus virtually concentrating the H_2O_2 and slowing down its decomp. LiOH, KOH and NaOH accelerate the decompn. of H_2O_2 , the speed increasing with the concn. of alkali. A very small amt. of Na_2O_2 also accelerated the decompn. The acceleration produced by alkalis was connected with the intermediate formation of a peroxide.

E. B. MILLARD.

The action of chlorine on sodium thiosulfate. P. A. W. SELF. *Pharm. J.* 95, 133-4(1915).—HCl and H_2SO_4 being set free, Na_2CO_3 is added to prevent their formation in the mixt. designed as a protection against inhaling Cl. S. found that in a mixt. of $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ 60, $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ 52, and H_2O 100 parts, the two salts are used up at about the same rate by Cl gas. A good proportion of glycerol should be added to keep the respirators wet. In a French formula, $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ 1000 g., $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ 200 g., H_2O 800 g., glycerol 150 g., the whole alkali was used up and the soln. turned acid when about 35% of the thiosulfate was decomposed by Cl. S. WALDBOTT.

Standardization of sodium thiosulfate solution for copper determination. W. G. GRANT. *Chem. Analyst* 13, 21(1915).—Weigh 10 g. pure Cu foil, dissolve in HNO_3 , evap. and allow to crystallize. Dissolve in water and dil. to 1000 cc. in standard

flask, taking pains to allow the soln. to come to room temp. before final diln. Use 10 cc. of this soln. for standardization.

H. M. LANCASTER.

The determination of lead as sulfite. G. S. JAMIESON. *Am. J. Sci.* 40, 157-60 (1915).—An exptl. study. Pb can be pptd. quantitatively from a slightly acid soln. with NaHSO_3 or $(\text{NH}_4)\text{HSO}_3$, or with aq. SO_2 , if the acidity of the soln. is carefully controlled. When a soln. contains much acid it should be almost neutralized with NH_4OH before attempting to ppt. the Pb (not applicable in the presence of H_2SO_4). To measured quantities of a $(\text{AcO})_2\text{Pb}$ soln. containing 10 g. of AcOH per l. add an excess of a 2% soln. of NaHSO_3 , stir thoroughly and allow to settle for an hr. or more, filter on gooches and wash with cold H_2O , taking care not to allow all the liquid to pass out of the crucible until the washing is completed. Dry crucibles + PbSO_3 for an hr. at about 150° and calc. to Pb. Working with a $\text{Pb}(\text{NO}_3)_2$ soln. containing 5 g. of HNO_3 per l. and pptg. with SO_2 soln. (36.8 g. SO_2 per l.), it is advisable to add about 10 cc. of 10% AcONa soln. after pptg. the PbSO_3 . Too great an excess of SO_2 will exert a solvent action on the PbSO_3 . Time of standing 10 min. to 1 hr. Similar results are obtained by nearly neutralizing the HNO_3 with NH_4OH and then adding NaHSO_3 . To sep. Cu and Pb, filter within 1 hr. leaving as much as possible of the ppt. in the beaker; wash once by decantation with about 10 cc. of H_2O , heat for about 5 min. with 10 to 15 cc. of $(\text{NH}_4)\text{HSO}_3$ soln. (prepared by passing SO_2 into NH_4OH (1:1) until strongly acid and then adding NH_4OH to neutralize the soln.). Transfer the ppt. to the gooch, wash with H_2O , dry, and weigh as PbSO_3 . In the presence of Ca, the PbSO_3 ppt. carries down CaSO_3 , although a Ca soln. gave no ppt. with NaHSO_3 , even after standing 2 days. Pb can be readily sepd. from Zn. Expts. indicate that Pb can be sepd. by means of NaHSO_3 without special precautions from those metals (except the alkali earth metals) which are not reduced by the sulfite. Attempts to titrate PbSO_3 with KIO_3 in the presence of strong HCl gave low results. Results of expts. reported show excellent agreement between amts. taken and found. Cf. Ivanov, C. A. 8, 2132.

F. W. SMITHER.

Analysis of some platinum minerals from the Urals and the method of separation of the platinum metals. IDE KOIFMAN. *Arch. sci. phys. nat.* 40, 22-38 (1915).—A new method for the analysis of native Pt, worked out as a thesis by V. THURINGER, is described. It is based on the sepn. of the elements into the groups: Os + Ir, Pt + Ir, Pd + Au, Rh + Cu, and Fe. Take a sample of about 12 g.; treat first with HNO_3 + HCl , Os and Ir remaining insol. Remove excess of acid from the soln. and ppt. the Pt and Ir with NH_4Cl ; these 2 metals can be sepd. by ignition of the ppt. and extn. by dil. HNO_3 + HCl , which dissolves the Pt. Treat the filtrate from the Pt and Ir with dimethylglyoxime, which ppts. Pd and Au; these can be sepd. by dissolving in HNO_3 + HCl , removing traces of Pt with NH_4Cl , and treating with $(\text{NH}_4)_2\text{C}_2\text{O}_4$, which ppts. Au. Treat the filtrate from the Pd and Au with Zn and HCl ; Rh and Cu, together with traces of Pt and Ir ppt. After ignition treat the metals with dil. HNO_3 , which dissolves Cu, leaving the others, which can be sepd. by fusion with $\text{K}_2\text{S}_2\text{O}_7$. Finally, oxidize the Fe and ppt. as basic acetate. This method was tried on known mixts. of the metals and found to give accurate results, and then extended to natural specimens from 6 localities, tables of the analyses of these being given. E. T. WHERRY.

The colorimetric determination of copper. G. DENIGÈS AND E. SIMONOT. *Bull. soc. pharm. Bordeaux* Aug.-Dec., 1915; *Répert. pharm.* 27, 172-3 (1915).—The process depends upon the production of a red-violet color by transforming Cu salts into CuBr_2 , dehydrating with H_2SO_4 and adding excess of KBr . To prepare the reagent, add 100 g. KBr free from BrO_3^- to 150 cc. boiled H_2O ; shake, transfer to a 200 cc. vol. flask, fill with warm H_2O , cool and make up to the mark with cold H_2O . To 20 cc. of this soln. in a beaker in an ice bath add slowly 10 cc. H_2SO_4 (d. = 1.84); cool and

filter off the K_2SO_4 with glass wool. Add 2 cc. of this soln. to 2 cc. of the Cu soln. to be tested, to which has been added 20% of its vol. of H_2SO_4 . Compare the color produced with that from a standard Cu soln. The reagent is unstable and should be kept in brown glass. Cu in complex compds. must first be electrolyzed. The method is adapted to detg. small amts. of Cu.

H. L. OLIN.

A rapid method for determining manganese in iron ores. C. H. FLECKINGER. *Chem. Analyst* 14, 7(1915).—*Soln. 1:* 350 cc. H_2O , 1400 cc. HCl (1.20), 350 cc. H_2SO_4 (1.84). *Soln. 2:* 1600 cc. H_2O , 400 cc. HNO_3 (1.42), 25 cc. of stock $AgNO_3$. *Soln. 3:* 200 g. $(NH_4)_2S_2O_8$ to 2000 cc. H_2O . *Soln. 4:* Weigh 3.225 g. $Na_4As_2O_8$ into a beaker and add approx. 100 cc. H_2O . Dissolve on steam or hot plate and dil. to 1250 cc. and keep as a stock soln. Dil. 125 cc. of this stock soln. to 2000 cc. and use for titration. Weigh 0.200 g. ore into a 250 cc. Erlenmeyer flask, add 15 cc. of soln. 1, cover with watch glass and boil on hot plate until dissolved. Remove watch glass and evap. until fumes of SO_2 are given off for 15 min. Remove to table and cool, add 100 cc. H_2O . Put on hot plate and boil. Add 20 cc. soln. 2, using a 250 cc. dispensing buret when required for detn. in large numbers. Allow to boil for 2 or 3 min. and add 20 cc. of soln. 3. Allow to foam for 10 seconds. Remove and cool. When cool, titrate with soln. 4, until pink disappears and is replaced by a pea green, which suddenly appears. It is more convenient to carry through this detn. in one flask. Many ores will probably not go into soln. in soln. 1. In such case, use 10 cc. HCl (1.20), then add 5 cc. of a soln. consisting of 1 part H_2O and 1 part H_2SO_4 (1.84). In ores containing between 2 and 6% Mn 0.100 or 0.050 g. should be taken, and standardized with an ore of the same percent.

H. M. LANCASTER.

A method for the separation of aluminium and zinc in aluminium alloys. H. C. WEIRICK. *Chem. Analyst* 13, 5-6(1915).—This method is based on the pptn. of Zn by H_2S from a soln. slightly acidified with H_2SO_4 , the amt. of Zn being approx. known. Dissolve alloy in dil. H_2SO_4 , neutralize with NH_4OH (Me-orange) and add dil. H_2SO_4 to make following amts. of acid, taking into consideration the H_2SO_4 liberated by the H_2S . In vols. less than 200 cc. 0.55 g. H_2SO_4 should be present per 100 cc.; 0.450 g. per 100 cc. in vols. of 300 cc., and 0.350 g. per 100 cc. in vols. of 500 cc. The amt. of H_2SO_4 liberated by H_2S can be calcd. by multiplying the approx. amt. of Zn by 1.5. Through the cool soln. pass a very rapid current of H_2S (at least 8 bubbles per sec.) for 40 min. Filter off the ZnS on a tared gooch, wash with cold H_2O , ignite in elec. muffle at 900° , and weigh as ZnO , or dissolve in HCl and titrate with $K_4Fe(CN)_6$. The Al can then be pptd. from the filtrate with NH_4OH , and detd. as Al_2O_3 in the usual way.

H. M. LANCASTER.

Analysis of aluminium. D. CHERCASS. *Chem. Analyst* 13, 12-4(1915).—Details for detn. of SiO_2 , Si, Cu, Fe, and Mn. Powdered Al used as a paint contains 2-5% stearic acid which acts as a binder. This may be extd. with ether in a soxhlet and weighed.

H. M. LANCASTER.

The determination of spelter coating on sheets and wire. J. A. AUPPERLE. *Am. Soc. Testing Materials; Metal Ind.* 13, 329-30(1915); *Iron Age* 96, 132(1915).—The Preece $CuSO_4$ test is unreliable. The $(AcO)_2Pb$ method yields accurate and satisfactory results, but the time required for making the test limits the scope of its usefulness. Proposed method for sheets: Cut several samples (usually 5) $2\frac{1}{4} \times 2\frac{1}{4}$ in. from various parts of the sheet, weigh together and immerse singly for one min. in 100 cc. of HCl (d. 1.20), to which has been added 5 cc. of $SbCl_3$ (20 g. Sb_2O_3 dissolved in 1 l. of HCl (d. 1.20)). The same 100 cc. of HCl can be used for at least 5 samples, but 5 cc. of the $SbCl_3$ soln. must be added for each sample. The samples are washed and scrubbed under running H_2O , dried with a towel, laid in a warm place for a few secs.,

and again weighed together. The number of g. lost is divided by the number of samples taken; each g. = 1 oz. of coating per sq. ft. The method is very accurate and more rapid than the Preece test. *Wire*: Strip a small section of the galvanized wire in HCl containing SbCl_3 . Then carefully measure the diam. of the black wire so that the length of wire to use may be detd.; it should be such that the number of g. of coating will represent the number of ozs. per sq. ft. of surface. These lengths are given in a table for 0 to 18 gage wire; in the lighter wires, it will be more convenient to use some fraction of these lengths. First clean the wire with CCl_4 or gasoline, weigh, place in a tall glass cylinder containing HCl (d. 1.20), to which has been added 2 to 3 cc. of the above SbCl_3 soln. After immersing the entire length of wire for one min. pour the acid soln. into another cylinder to facilitate removing the wire; scrub under running H_2O , dry, and weigh as above. Each g. lost = 1 oz. of coating per sq. ft. For direct comparison with the wt. of coating as expressed on galvanized sheets (2 sides), this figure should be doubled.

F. W. SMITHER.

A rapid method for washing gold beads. E. J. HALL. *Eng. Mining J.* 100, 149-50 (1915).—The method of Black (*C. A.* 9, 573) is modified by inserting a vacuum regulator in the line beyond the suction bottle, and by the use of a liquid-dispensing bottle (an inverted bottle with bottom cut off and a valve made from a glass rod and tube cemented into neck).

F. W. SMITHER.

Zinc dust precipitation tests. N. HERZ. *Bull. Am. Inst. Mining Eng.* 1915, 1507-13.—Sharwood's method (cf. *C. A.* 6, 1415) consists in digesting 0.5 g. of the sample in 250 cc. of a soln. contg. 15 g. $\text{KAg}(\text{CN})_2$ and 1.5 g. KCN per l., agitating frequently for 2 hrs., filtering, adding test Pb, scorifying and cupelling. $\text{Mg Ag} \times 0.0606 = \% \text{ pptg. efficiency}$. H. advises using a soln. of double this strength in Ag, adjusting to 0.2% free NaCN, adding a slight excess $\text{Ca}(\text{OH})_2$ soln. to causticize carbonates, filtering, and then by addition of acid bringing the protective alkalinity to equivalent of 0.01 to 0.015% NaOH. With soln. so prepd., the test is made as described by Sharwood. Results are more uniform and more in accord with actual practice. Efficiency should be over 40%. Most of the dust (95 to 99%) should pass 200-mesh. ZnO should be low (well under 15%). Over 1% Pb should be present; as high as 4% may do no harm. Cd may partially take the place of Pb. The dust sometimes contains oil which may be detected or detd. by extn. with ether. It makes the action slow; a partial remedy is to expose the moistened dust to air for some hrs. When dry, the dust does not oxidize, but it may easily be ruined by long exposure to moist air.

E. WALLER.

Detection of various mineral and alkaloidal poisons in waters. P. BRETEAU. *J. pharm. chim.* 12, 68-73 (1915).—A scheme is given for the systematic sepn. of certain alkaloids (brucine, colchicine, atropine, morphine, strychnine, veratrine) from Cu, Sb and As in one sample of 500 cc. of H_2O with test for each substance named; and the sepn. of Ba, cyanides, Hg, Pb and Zn in another 500 cc. of the same H_2O . S. W.

Characterization of hydrocyanic acid in toxicology by the ferric thiocyanate test. P. LAVIALLE AND L. VARENNE. *J. pharm. chim.* 12, 74-81 (1915).—To the cold soln. containing HCN or its alk. salts, add an amt. of $(\text{NH}_4)_2\text{S}$ sufficient to give a distinctly yellow color to the subsequent evapn. residue. Boil gently for 5 min. in a porcelain dish and then evap. on a water bath to about 1 cc. Add about 9 cc. of H_2O , 10 drops of concd. HCl, stir and add 20 cc. of Et_2O . Shake, and decant the Et_2O into a porcelain dish. Repeat this twice with 10 cc. of Et_2O . Evap. the united Et_2O exts. rapidly at ordinary temp. and test with FeCl_3 immediately to avoid evapn. of HCNS. Add the official FeCl_3 soln., dild. 1:10, drop by drop by means of a glass rod until the red coloration no longer deepens. Add at once 1 or 2 cc. of Et_2O , stir and pour into a test tube; observe the violet-red soln. of $\text{Fe}(\text{CNS})_3$ in Et_2O . Ferric meconate, similar in

color, is insol. in Et_2O , and is not decolorized, as is $\text{Fe}(\text{CNS})_3$, by a 1:10 soln. of AuCl_3 . The method detects 0.00005 g. HCN in 10 cc., and is about 20 times as sensitive as the Prussian blue test.

S. WALDBOTT.

Estimation of raffinose by enzymotic hydrolysis. C. S. HUDSON AND T. S. HARDIN. *J. Am. Chem. Soc.* 37, 2193-8(1915); cf. *C. A.* 9, 1342.—The method depends upon the conversion of the raffinose by invertase (ext. from top yeast, rich in invertase and quite free from melibiase) into melibiose + fructose and accurate measurement of the conversion of melibiose into galactose + glucose by the melibiase obtained from bottom yeast, which is free from maltase, cellulase, lactase, trehalase, inulase or diastase. The only known substance which may interfere is melibiose itself, but since it reduces Fehling soln. and raffinose does not, it may be excluded from consideration in some cases. The soln., clarified if necessary with neutral $\text{Pb}(\text{OAc})_2$ and freed from excess of Pb as oxalate or sulfide, dild. so as not to contain more than 13% total sugars, accurately neutralized and then made slightly acid with 1-2 drops glacial AcOH per 100 cc., is treated, for every 95 cc., with 5 cc. of top yeast invertase soln. and a few cc. toluene and kept at room temp. until the rotation is const. (usually 12-24 hrs.); to 95 cc. is now added 5 cc. of bottom yeast ext. and the change in rotation from the instant of mixing accurately detd. from day to day, the temp. being carefully controlled for the readings (the data in this paper were obtained at 20°). Each degree Ventzke change in rotation corresponds to 0.239 g. melibiose or 0.352 g. anhydrous raffinose per 100 cc. in a 2 dcm. tube. Careful manipulation and several days' waiting are required, but this is fully repaid by the accuracy and certainty of the results. The method has been found quite accurate with mixts. of sucrose and raffinose containing even as little as 0.5 part of the latter to 100 of the former, and also in mixts. with sucrose + glucose, invert sugar, lactose, maltose, cellose or trehalose. C. A. R.

Determination of formic acid in the presence of acetic acid. R. LAUFFMANN. Freiberg. *Chem. Ztg.* 39, 575(1915).—L. finds that in Heermann's method the AcOH is not quite all expelled even by several evapns. with HCO_2H . J. H. MOORE.

The quality of platinum ware (BURGESS) 1. Sampling in colliery work (GREGORY) 21.

8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY.

Analyses of rocks and minerals from the laboratory of the United States Geological Survey, 1880 to 1914. F. W. CLARKE. U. S. Geol. Survey, *Bull.* 591, 376 pp. (1915).—A tabulation of 2789 analyses, 714 of which are of minerals. R. C. W.

Bournonite crystals of unusual size from Park City, Utah. FRANK R. VAN HORN AND W. F. HUNT. Case School and Univ. Mich. *Am. J. Sci.* 40, 145-50(1915); cf. *C. A.* 8, 3281.—The crystallography of 3 large crystals of bournonite from the Silver King Coalition Mine is given. Analysis by W. R. Veazey of a specimen found at the Daly West Mine gave Pb 43.18, Cu 13.14, Sb 25.03, S 19.59, sum 100.94; sp. gr. = 5.829; this agrees closely with the theory for PbCuSbS_4 . L. W. RIGGS.

A manganese diopside from Radautal in Harzburg. J. UHLIG. Bonn. *Neues Jahrb. Min. Geol.* 39 (Beil.-Bd. *Bauer Festschrift*) 446-9(1914).—Analysis of pale red pyroxene gave SiO_2 51.92, TiO_2 0.31, Al_2O_3 2.54, FeO 6.16, MnO 1.08, MgO 12.49, CaO 24.76, loss on ignition 0.44. Sp. gr. = 3.30-3, $n = 1.68$, double refraction high, pleochroic rose, to almost colorless, to reddish lilac. W. H. FRY.

Plumbojarosite and other basic lead-ferric sulfates (vegasite) from the Yellow Pine District, Nevada. ADOLPH KNOPF. U. S. Geol. Survey. *J. Wash. Acad.* 5, 497-503 (1915).—The plumbojarosite previously noted (*C. A.* 9, 1591) is fully described. A very complete analysis by R. C. Wells is given; the most noteworthy features are the low Fe_2O_3 , the high Bi_2O_3 (6.34%) and the presence of CuO (1.97%). On removing impurities and recalcd. to 100%, and then considering the CuO to be present as beaverite, some grains of which could be recognized under the microscope by their n ($\omega = 1.84$) being less than that of the plumbojarosite ($\omega = 1.872-6$), the mineralogical comp. of the material was found to be 80.58% plumbojarosite and 20.01% beaverite. *Vegasite*: Named from Las Vegas, the principal town near which it occurs; pronounced Văgasit; color, straw yellow; luster, ochreous; structure cryptocrystalline; H., not detd. Sp. gr. = 3.458; under microscope, pleochroic brownish to pale yellow with absorption $\omega > \epsilon$; $\omega = 1.82 \pm 0.01$, $\epsilon = 1.755 \pm 0.002$, opt. + uniaxial; system, hexagonal; habit, minute tabular 6-sided plates, appearing like fibers in end view, qualitatively behaves like plumbojarosite, giving reactions for Fe'' , Pb and SO_3 ; analysis, by R. C. Wells: SiO_2 1.14, Fe_2O_3 38.90, Al_2O_3 3.33, H_2O (—) 0.94, H_2O (+) 10.77, SO_3 24.60, PbO 18.44, Na_2O 0.76, K_2O 0.10, CaO 0.45, MgO 0.49, sum 99.92; this is probably best interpreted as a basic sulfate, $\text{Pb}[\text{Fe}(\text{OH})_2]_4(\text{SO}_4)_2 + 10\%$ colloidal $(\text{Fe}, \text{Al})(\text{OH})_3$.
E. T. W.

Geological anatomy of a Tennessee zinc mine. FRANK L. NASON. West Haven, Ct. *Eng. Mining J.* 100, 259-62 (1915).—Continuation of *C. A.* 9, 1591. The position of the ores in the New Prospect Mine is described in detail and shown to agree with the profound-fissure theory of origin previously advocated.
E. T. W.

Nitrate deposits in southern Idaho and eastern Oregon. G. R. MANSFIELD. U. S. Geol. Survey, *Bull.* 620B, 19-44 (1915).—At Homedale, Idaho, NaNO_3 and KNO_3 are found in veinlets 1-8 mm. thick in rhyolite rock over a considerable area. Other localities of the region have similar deposits. These deposits at the best, however, amount to only about 1% of the whole rock. No positive statement can be made about the extent of the nitrates until more work has been done in opening up the nitrate-bearing zones. The presence of certain other salts suggests that the deposits are due to the action of percolating waters but whether the N was conc. by organic agencies or came from a volcanic source as nitrides cannot be definitely stated.

R. C. WELLS.

Anticlinal structure in parts of Cotton and Jefferson Counties, Oklahoma. C. H. WEGEMANN. U. S. Geol. Survey, *Bull.* 602, 108 pp. (1915).—A report of geol. exploration of a region not yet known but suspected to contain oil or gas, pointing out especially the anticlines and domes which are without doubt one of the important factors conditioning the presence of hydrocarbons in commercial quantities.
R. C. WELLS.

Crystallization of haplobasaltic, haplodioritic and related magmas. N. L. BOWEN. Geophys. Lab. *Am. J. Sci.* 40, 161-85 (1915); cf. *C. A.* 7, 2735; 8, 2856, 3543.—"Though 5 oxides enter into the comp. of the mixts. studied, yet all the phases appearing can be expressed quantitatively in terms of 3 components. . . . From the phase rule point of view, then, the mixts. studied constitute the ternary system diopside-anorthite-albite. In this research the quenching method was used exclusively, and was calibrated against the following fixed points: gold—1062.5°, Li_2SiO_3 —1201°, diopside—1391.5°, anorthite—1550°. Three binary systems were first studied, viz., anorthite-albite, anorthite-diopside, and albite-diopside; and the findings shown in tables and by curves. The results of a study of the ternary system albite-diopside-anorthite are shown in 9 equilateral triangle diagrams and several tables. The facts detd. for haplodiorite, etc. (*haplo* = simple) are applied to their natural analogs, and it is shown

that there can be little reason to doubt that crystn. controls the differentiation of the subalk. series of igneous rocks." L. W. RIGGS.

Granite from Tatra. Review of results obtained so far. J. MOROZEWICZ. *Kraukau. Neues Jahrb. Min. Geol.* 39 (Beil.-Bd., *Bauer Festschrift*), 290-345 (1914).—M. gives 16 analyses of granite, oligoclase, orthoclase, biotite, muscovite, biotite-oligoclase-pegmatite, oligoclase-orthoclase-pegmatite, oligoclase-albite-pegmatite, albite-microcline-pegmatite, and albite-orthoclase-pegmatite. W. H. FRY.

Northfieldite, pegmatite, and pegmatite schist. B. K. EMERSON. Amherst, Mass. *Am. J. Sci.* 40, 212-7 (1915).—*Northfieldite* is the name given by E. to an igneous rock composed of quartz and mica occurring in Pelham and Northfield, Mass. Analysis by E. T. Allen of av. rock from Pelham gave SiO_2 93.38, Al_2O_3 3.09, Fe_2O_3 + FeO 0.72, TiO_2 0.12, CaO 0.34, MgO 0.43, Na_2O 0.50, K_2O 1.32, sum 99.90. The rock is regarded as a differentiation product of a magma, though unlike pegmatite in the absence of feldspar. L. W. RIGGS.

The elaeolite syenite laccolith of Serra de Monchique, southern Portugal. ERICH KAISER. Giessen. *Neues Jahrb. Min. Geol.* 39 (Beil.-Bd., *Bauer Festschrift*), 225-67 (1914).—A discussion of some hot springs and their waters is included. W. H. FRY.

The noselitephonolites of the Schellkops near Brenk. W. ZANTINI. Bonn. *Neues Jahrb. Min. Geol.* 38, 587-642 (1915).—The rocks show the typical structure of noselitephonolites and vary in color from light yellow to deep brown. Masses of blue black noselite and clear colorless sanidine are apparent to the eye while microscopic exam. reveals the presence of nepheline, leucite, pyroxene and very small amts. of biotite and magnetite. Zeolites and calcite are secondary minerals formed by the action of H_2O and the atmosphere. Analyses are given, the striking feature being the high % of alkalis present. In a yellowish brown phonolite, poor in leucite, the percentages of Na_2O and K_2O were 8.88 and 9.53, respectively; in a dark bluish gray sample, rich in leucite, they were 8.83 and 9.10, respectively. H. W. DAUDT.

The basalts of the Marburg region. ARTHUR SCHWANTKE. Analyses. KARL GUYOT. *Neues Jahrb. Min. Geol.* 39 (Beil.-Bd., *Bauer Festschrift*), 531-67 (1914).—Analyses are given, which prove the near relationship of several basalts and dolerites to each other. W. H. FRY.

Nepheline basalt in the Fort Hall Indian Reservation, Idaho. GEORGE R. MANSFIELD AND ESPER S. LARSEN. U. S. Geol. Survey. *J. Wash. Acad.* 5, 463-8 (1915).—The field occurrence of the rock is described and an analysis given, the relations to previously described rocks being discussed. In the C. I. P. W. system its systematic position is (III) IV.1.(2), '2.(1).2; Rossweinese. Comparison of the norm (the minerals which ought to be present, according to the C. I. P. W. interpretation of the analysis) with the mode (the minerals shown by microscopic exam. to be actually present) "indicates that the norm shows more magnetite, forsterite and feldspar than the mode and less biotite, diopside and nepheline." E. T. W.

Scapolite-bearing eruptives from the Lake Laach region. R. BRAUNS. Bonn. *Neues Jahrb. Min. Geol.* 39 (Beil.-Bd., *Bauer Festschrift*), 79-125 (1914).—B. gives several analyses of the rocks of this area. W. H. FRY.

Alcyonaria as a factor in reef limestone formation. L. R. CARY. Princeton Univ. *Proc. Nat. Acad. Sci.* 1, 285-9 (1915).—C. presents a study of those species of *Alcyonaria* whose limy secretion, in the form of minute spicules, is set free at the time of disintegration of the tissues of the living colony, leaving no recognizable skeleton. Members of the family Gorgonaceae are more abundant on coral reefs than those forming a massive skeleton. It was found that by dissolving the organic matter in 25% NaOH , the dried spicules in 12 detns. avd. 27.4% of the wt. of the wet colonies. Observations

on reefs about Tortugas, in which the gorgonian colonies on 20 representative sq. yds. were counted, showed that the spicule content of the living gorgonians amounted to 5.28 tons per acre. Overgrowth of gorgonian tissue by other organisms causes death by chem. means or by exclusion of food and O. The rate of addition of the spicules to reef formation is varied by storms. After the hurricane of Oct. 17, 1910 the amt. set free reached 25 lbs. per sq. yd. L. W. RIGGS.

A peculiar oolite from Bethlehem, Pennsylvania. EDGAR T. WHERRY. *Proc. U. S. Nat. Museum* 49, 153-6(1915).—The material described occurs in a quarry in magnesian limestone. In one layer the ooids are divided parallel to the bedding into a light and dark portion, the latter being the lower. Analyses show the limestone of this bed to contain CaO 33.10, MgO 17.84, FeO 0.25, CO₂ 45.70, Al₂O₃ 0.23, Fe₂O₃ 1.33, SiO₂ 0.52, H₂O 0.32, C 0.79, sum 100.08; while the ooids which have weathered out contain CaO 30.40, MgO 19.71, FeO 0.11, CO₂ 45.57, Al₂O₃ 0.32, Fe₂O₃ 1.90, SiO₂ 0.68, H₂O 0.44, C 1.21, sum 100.34. By calcg. the mineral comps. from the above analyses, and also the comp. of the matrix, assuming that the ooids make up half of the rock, it is shown that the ooids are higher in dolomite, quartz, kaolin, limonite and carbon, and lower in calcite and siderite than the matrix. This oolite has probably formed by soln. of original aragonite, causing the insol. C and nuclei to fall to the bottom of the cavities; secondary dolomite subsequently filled the latter, and still later the C pptd. some pyrite, which has altered to limonite. Figures are given to bring out the various stages of the process. L. W. RIGGS.

Platinum minerals from the Urals (KOIFMAN) 7.

9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

Table for rapid method of calculating furnace additions. J. W. BUMGARDNER. *Chem. Analyst* 13, 19-20(1915).—Convenient for furnace foremen in foundry work, facilitating calculations. H. M. LANCASTER.

The metal mixer. F. C. THOMPSON. *Iron Coal Trades Rev.* 91, 33-5(1915).—T. points out the disadvantages of using direct blast-furnaces and cupola melted metal in the Bessemer and outlines the history of the mixer. The modern type of mixer has become practically an open-hearth tilting furnace of large size and deep bath of metal in which some of the reactions of the open-hearth furnace take place. In the new types 80% of the S is removed, combining with Mn to form a light slag. The remarkable uniformity of mix obtained increases the output of the converter greatly and causes the linings and bottoms to last 30% longer. Used in open-hearth practice, the preliminary purification, in which most of the Si, P and Mn are eliminated at relatively low temps. (1400°) leaving only C to be oxidized in the furnace proper, increases the efficiency of the process. H. L. OLIN.

Selecting refractories for the foundry. W. H. KELLEY. *Chem. Eng.* 22, 82-4 (1915); see C. A. 9, 47. E. J. C.

Roasting and leaching concentrator slimes tailings. L. ADDICKS. *Bull. Am. Inst. Mining Eng.* 1915, 1471-84.—The original ore consists of pyrite and chalcocite disseminated through the gang and contains approx. Cu 2.35, S 3, Fe 1.5, Al₂O₃ 13, SiO₂ 70%, Ag 0.05 oz., Au none. The concentrates by flotation are of high grade. Tailings consist of about half sand running 0.3% Cu (discarded) and half slimes carrying about 1% Cu. Exptl. runs were made on these slimes. The wet slimes could not be thickened beyond 45% H₂O without some segregation and unevenness of classifica-

tion. Details as to expts. in drying by sun and wind are given. Burying hot steam-coils in the cars of material when loaded for transportation to the plant brought the moisture down to 25%, and in that form it was charged into the roaster. This is a 6-hearth, 18-ft. MacDougall app. oil-fired at the 3rd hearth. Max. temp. on any hearth is 950° F. The hot calcines are discharged into the spent liquor from electrolyzing tank containing about 3% H_2SO_4 in a 30-ft. triangular trough which conducts to Dorr thickeners in which wood has been substituted for metal in the under-liquor parts. About 90% of the leaching took place in this trough. In the thickeners a diaphragm pump was tried, and the remaining air lifts were arranged to return a part of the underflow to the same tank; otherwise the air lifts work irregularly and unsatisfactorily. Leached out as sulfates in lbs. per ton of slimes Cu 10, Fe 4.3, Al_2O_3 16.2. Acid used was 49 lbs. indicating that the equiv. of about 20 lbs. H_2SO_4 came from the calcines, which was much better than had been shown by lab. tests. Some of the Cu was sepd. as cement to keep the Fe and Al in the electrolyzed liquor down to the desired point.

E. WALLER.

Low-grade complex ores of Park City, Utah. S. S. ARENTZ. Univ. Utah. *Mining Eng. World* 43, 252-5(1915).—A discussion of the methods by which values can be recovered from various low-grade ores and tailings from the treatment of high-grade ones.

E. T. WHERRY.

Flotation at Washoe Reduction Works, Anaconda. E. P. MATHEWSON. *Mining Sci. Press* 111, 312-3(1915).—An illustrated description.

E. J. C.

Flue dust sintering plant at Gary. *Iron Age* 95, 1168-70; *Iron Trade Rev.* 56, 1020(1915).—Two 9 X 90 ft. rotary kilns, revolving 1 r. p. m., burning coke oven gas and sinter dust from all furnaces.

H. V. MAIN.

Blast furnace slag handling system. F. L. PRENTISS. *Iron Age* 95, 1396-8(1915).—In the Croxton system chains placed in slag beds are pulled up through cooled slag, breaking it enough to be handled by a crane. This method reduces the H_2O content as compared with granulation, eliminates danger and reduces shipping cost.

H. V. MAIN.

The Tonapah plant of the Belmont Milling Co. A. H. JONES. *Bull. Am. Inst. Mining Eng.* 1915, 1731-58.—Ore is crushed to pass 1 in. apertures in trommel before feeding to the stamps where it is stamped wet (5 pts. of soln. to 1 of ore). Soln. has strength of 5 lbs. KCN and 1 lb. CaO. By grinding in tube mills it is brought to a condition such that 75% passes 200-mesh. At this stage, CaO and 0.15 lb. Pb acetate per ton are added. Then it is run onto Wilfley tables. The concentrates, which contain about 30% each of Fe, S and insol. and 1.6% Au and Ag, are partly dried out and shipped to the smelter. The slimes from the classifiers, Dorr thickeners and concg. tables are treated in thickeners, the overflow from the first of these going to circulating tank or pptn. supply tanks, the underflow to the air agitators. After passing the 6th agitator, the pulps are diluted with partially pptd. soln. and then, thickened. To the No. 1 agitator KCN is added to bring the strength up to 6 lbs. per ton of soln.; also 0.18 lb. Pb acetate is added. Filtration is effected with vacuum filters. After clarifying, one portion is completely pptd., another only partially, the soln. being used on concg. tables, tube mill feed, etc. Zn consumption is 0.7808 oz. per oz. of bullion. The pptn. presses are cleaned every 15 days. The ppt. is briquetted. The flux consists of borax 2.45, Na_2CO_3 6.05 and SiO_2 6%; it is fused in corundum-lined Rockwell oil furnace. The completely pptd. product contains Au and Ag 74.23%, Pb and Cu over 2% each, Zn 4.70, Se 1.40. Bullion contains Au and Ag 93.23, Pb 2.41, Cu 1.02, Se 1.80%. Pb acetate gave much better results than PbO or $Pb(NO_3)_2$. Pb tends to aid extn. by forming PbS with sulfides of the ore; Zn seems to act similarly to some extent. Nevertheless some KCNS always appears in the mill solns. Re-

pptn. of Au and Ag will occur when the alkalinity is too great or too small. Between 0.8 and 1.5 lbs. per ton of soln. was found to be a safe limit. Refinery slags are ground in a ball mill, and concd. on a Wilfley table. The concentrates are briquetted with the product for the next melt. Tailings are sent to the smelter. When fed into the mill circuit, they caused an undesirable accumulation of Cu in the solns. E. WALLER.

The Engels mine and mill. T. T. READ. *Mining Sci. Press* 111, 167-71 (1915).—The important primary minerals in the ore are bornite and chalcopyrite, with associated magnetite; secondary chalcocite and covellite have been derived by upward secondary enrichment; near the surface the ore has been oxidized to malachite, though azurite, cuprite, and native Cu are also found. Flotation yields a 40% Cu concentrate from a mill feed averaging slightly less than 4% Cu, the magnetite going into the tailing. The ore, after being crushed to such a fineness that only 5% remains on 100-mesh and 65% of it will pass 150-mesh, goes to a 12-cell standard Minerals Separation flotation machine. 0.4 lb. of oil per ton of ore is added, half to the tube mill and remainder to the different cells. The froth from the first 3 cells is drawn off as a finished concentrate; that from the remaining cells is returned to the first cell for retreatment. Total extn. averages 84%. Cu sol. in dil. H_2SO_4 ranges from 0 to 0.4%, about $\frac{2}{3}$ of which is recovered. The concentrate froth is sent to a settling tank and the thickened froth then goes to an Oliver filter, producing a cake averaging 10 to 12% H_2O . This concentrate is dried to 5 to 6% H_2O basis, sacked, and shipped to smelter.

Brit., 8,826, Apr. 7, 1914. D. R. JAMES. Coating metals such as Fe, steel, Cu, and other plates, with Sn, terne, or other metal or alloy, on one side only, by passing the plate between pairs of rolls, one roll of each pair being of steel or other material which picks up the molten coating metal and applies it to the plate, and the other roll of each pair being of china, glass, marble, granite, or other stone or material to which the coating metal does not adhere. The lower rolls are immersed for part of their depth only in the molten metal, and the upper rolls of glass, etc., are wholly immersed in palm oil, resin, or other flux. The plates pass out of the pot through finishing-rolls, one roll of each pair being of steel, etc., and rotating in troughs containing coating-metal, and the other roll of each pair being of material to which the coating-metal does not adhere.

Brit., 9,049, Apr. 9, 1914. AMALGAMATED ZINC (DE BAVAY'S), LTD. In con-

concentrating ores, sulfide ores, especially blende and galena, after treatment by a flotation process for the removal of most of the gang are sepd. from one another by a flotation process in a dil. soln. of Na_2CO_3 , whereby the galena is wetted and a froth rich in blende and a residue rich in galena are obtained. If an organic frothing-agent has been used in the preliminary flotation process, the concentrates may be subjected, before sepn. in the Na_2CO_3 soln., to agitation with a soln. of H_2S , Na_2S , or NaHS , to which may be added weak Na_2CO_3 soln. The sepd. products may be subjected to a repetition of the treatment.

Brit., 9,535, Apr. 17, 1914. W. BORCHERS. In smelting ores, etc., containing Ni, Fe and Cu sulfides, for the production of nickel-iron alloys, the carbonaceous reducing agent is caused to act slowly so as first to reduce Fe and subsequently Ni, while Cu is left in the slag. For this purpose, the ore is melted down with an excess of lime in an elec. furnace lined with C; poor ores may first be converted into mat to increase the Cu-Ni content.

Biochemical synthesis of *d*-glucosides of monovalent alcohols. II. α -Glucosides. EMIL BOURQUELOT. *Ann. chim.* 3, 287-337(1915).—A collective article. L. E. W.

Glucosidification of glycerol by means of α -glucosidase. E. BOURQUELOT, M. BRIDEL AND A. AUBRY. *Compt. rend.* 161, 41-3(1915).—Just as emulsin acting upon glycerol-glucose mixts. leads to the formation of a mixt. of monoglucosides, α -glucosidase ("bottom yeast") acting upon a mixt. of glycerol and glucose (in the presence of PhMe) gave rise to a mixt. of α -monoglycerides. The proportions used in the synthesis and the methods of isolating the monoglyceride mixt. (A) were very similar to those previously used in the prepn. of the β -glucosides (cf. C. A. 9, 2521). The mixt. (A), when dried at 100° , was slowly hydrolyzed by concd. "bottom yeast" preps., as shown by the gradual change in $[\alpha]_D$ and the amts. of glucose liberated. Judging by the polarimetric readings made at intervals during the hydrolysis of (A), B. and A. conclude that (A) probably contains 2 monoglucosides, one having $[\alpha]_D > 129^\circ$, the other $[\alpha]_D < 120^\circ$. No direct method of sepg. the glucosides in (A) proved available. LOUIS E. WISE.

Symmetrical bitertiary glycols. M. BOUVET. *Bull. soc. chim.* 17, 202-16(1915).— $[\text{Me}_2\text{C}(\text{OH})\text{CH}_2\text{CH}_2]_2$ (A), rectangular leaflets with $2\text{H}_2\text{O}$, m. 59° , anhydrous, m. 92° , was prepd. by treating MeMgI in dry Et_2O with Et adipate (Zelinski, *J. Russ. Phys. Chem. Soc.* 38, 931, gives 94°). When HCl gas acts upon (A) in ice-cold, dry PhMe or in abs. alc., 2,7-dichloro-2,7-dimethyloctane (B), m. 49° , possessing an odor suggesting musk, is formed. Diacetate of (A), b. $150.5-1.0^\circ$. $\text{C}_8\text{H}_{18}\text{N}$ when heated with (B) in alc. on the H_2O bath for 10 hrs. gave rise to 2,7-dimethyl-2,7-octadiene, $(\text{Me}_2\text{C}:\text{CH}.\text{CH}_2)_2$, b. $163.5-4.5^\circ$, whose CHCl_3 soln. absorbs 4 atoms Br. The following diols were prepd. by the action of suitable alkyl or aryl Mg halides upon Et adipate: $[\text{Et}_2\text{C}(\text{OH})\text{CH}_2\text{CH}_2]_2$, rhombohedrons, m. $72-3^\circ$ (cf. Valeur, *Compt. rend.* 132, 834); 4,9-dipropyl-4,9-dodecanediol (tetrapropylhexanediol), $[\text{Pr}_2\text{C}(\text{OH})\text{CH}_2\text{CH}_2]_2$, m. 93° ; 1,1,6,6-tetraphenyl-1,6-hexanediol (C), m. 211.5° (without decompn.), giving an orange-red color with H_2SO_4 . Ph_2 was an important by-product in the synthesis of (C). When boiled under reflux with AcOH or AcOH-HCl, (C) is dehydrated with the formation of 1,1,6,6-tetraphenylhexane-1,6-diene (D), $[\text{Ph}_2\text{C}:\text{CH}.\text{CH}_2]_2$, crystals

with green reflex, m. 108° , readily adding Br with the formation of a tetra(?) - Br deriv., m. 140° (decompn.), in striking contrast to $[\text{Ph}_2\text{C}:\text{CH}]_2$ which adds no Br (cf. Valeur, *Compt. rend.* 136, 694). By reducing (D) in AmOH with Na is obtained 1,1,6,6-tetra-phenylhexane, m. 104° , adding no Br. On oxidation with KMnO_4 , (D) in acetone gives rise to a mixt. of BzPh and $[\text{CH}_2\text{CO}_2\text{H}]_2$, a reaction which shows the possibility of forming a dibasic acid of lower C content, $(\text{CH}_2\text{CO}_2\text{H})_2$, from a higher homolog, $(\text{CH}_2\text{CH}_2\text{CO}_2\text{H})_2$, by passing through the intermediate products (C) and (D). 1,1,6,6-Tetrabenzylhexane-1,6-diol, needles from acetone, m. $181.5-2.0^{\circ}$. 1,1,6,6-Tetracyclohexylhexane-1,6-diol, m. 158° , cyclohexene, b. $83-4^{\circ}$, $\text{C}_6\text{H}_{11}\text{OEt}(\text{?})$, b. 149° , and a mixt. of unidentified products possessing an odor suggesting H_2S were formed by the interaction of $\text{C}_6\text{H}_{11}\text{MgCl}$ and Et adipate.

Structure of magnesium-organic complexes and mechanism of their formation. V. CHELINTZEV. Moscow. *J. prakt. Chem.* 89, 86-92(1914).—A critical discussion in which C. refutes the claims of G. Stadnikov regarding the mechanism of the formation of Mg-org. complexes. Cf. C. A. 7, 983.

D. BREESE JONES.

p-Cyano- and *p*-carboxymalachite green. BERTHOLD RASSOW AND HERMANN GRUBER. *J. prakt. Chem.* 91, 341-57(1915).— $\text{p-NCC}_6\text{H}_4\text{CHO}$ (a), previously prepd. by Reinglass (*Ber.* 24, 2423) and Hantzsch (*Z. physik. Chem.* 13, 522), is obtained more smoothly in the following manner: To 50 g. *p*- $\text{NH}_2\text{C}_6\text{H}_4\text{CHO}$ in 200 g. HCl (d. 1.19), after shaking well during 4 hrs., 600 g. H_2O are added and the cold soln. diazotized, adding the pulverized NaNO_2 in 1.0-2.0 g. portions. The soln. is then filtered, freed from the excess of HNO_2 with $\text{CO}(\text{NH}_2)_2$ and then added slowly with continuous stirring at -2° to a soln. of $\text{KC}(\text{CN})_2$ at -2° to -5° , prepd. from 119 g. $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$, 625 g. H_2O and 131 g. KCN. Ice is added during this operation, which requires 2 to 2.5 hrs., the mixt. then packed in ice 12 hrs., (a) extd. with Et_2O after adding NaCl or a little concd. HCl to facilitate sepn., completely dried over CaCl_2 , the Et_2O removed, and the red oil distd.; it b. 133° ; yield, 45%. 4 g. (a) condenses with 10 g. PhNMe_2 in 4 g. 93% alc. in the presence of POCl_3 (ZnCl_2 gives only about a 60% yield). On making alk. with NaOH, 4',4'-di[*dimethylamino*]-4'-nitrotriphenylmethane (b) seps. in almost theoretical yield as a yellow oil, crystals on standing; yellow crystals from alc., m. $158-60^{\circ}$. (b) is oxidized by freshly prepd. $\text{MnO}(\text{OH})_2$ (*Ber.* 19, 744) at $40-60^{\circ}$ in the presence of 25% H_2SO_4 (3 mols.) to 4',4'-di[*dimethylamino*]-4'-nitrotriphenylcarbinol (c), which is pptd. by KOH, dried, extd. from inorganic substances with C_6H_6 , and pptd. by low boiling petr. ether; it m. 132° . (Twice the theoretical quantity of $\text{MnO}(\text{OH})_2$ should be employed, even though part of (b) is oxidized too far, for a mixt. of (b) and (c) is very difficult to sep.). Dihydrochloride (d), $\text{HOC}(\text{C}_6\text{H}_4\text{CN}) \cdot [\text{C}_6\text{H}_4\text{NMe}_2\text{HCl}]_2$, from (c) in abs. Et_2O with dry HCl, seps. as a grayish amorphous powder. The chloride of the dye base (e), $\text{C}(\text{C}_6\text{H}_4\text{CN})[\text{C}_6\text{H}_4\text{NMe}_2] \cdot \text{C}_6\text{H}_4\text{NMe}_2\text{Cl}$, seps. as a bronze-colored mass when (d) is dissolved in high % alc. and Et_2O added. The picrate of (c), which is pptd. in alc. soln., is greenish white and unstable. It decomp. almost immediately into the dye salt, bronze-colored leaves from alc., turning dark green in the air, which m. $188-90^{\circ}$. (c) forms an oxalate, when a soln. of anhydrous $(\text{CO}_2\text{H})_2$ in dry Et_2O is added to a H_2O -free soln. of (c); it is a greenish white salt, changing very quickly into the dye salt, which seps. on evapn. of the alc. soln. as a sticky, bronze-colored mass. It m. (decompn.) at a low temp., leaving a residue m. 172° . 4',4'-Di[*dimethylamino*]triphenylmethane-4'-carboxylic acid (f) is obtained in nearly theoretical yield when 5 g. (b) in 100 g. alc. are heated with 20 g. KOH in 100 g. alc. until nothing seps. on cooling; the alc. is then removed, the residue dissolved in H_2O , and (f) pptd. with a slight excess of H_2SO_4 , needles from abs. alc., m. 252° , sol. in H_2SO_4 with a yellowish green color; the potassium salt seps. from H_2O as a voluminous ppt. Malachite green *p*-carboxylic acid bisulfate (g), $\text{C}(\text{C}_6\text{H}_4\text{CO}_2\text{H})(\text{C}_6\text{H}_4\text{NMe}_2) \cdot \text{C}_6\text{H}_4\text{NMe}_2$.

$\text{NMe}_2\text{SO}_4\text{H}$, is formed when (f) is suspended in H_2O with sufficient 25% H_2SO_4 for both salt formation and decompn. of the oxidizing agent, treated in portions with twice the theoretical quantity of $\text{MnO}(\text{OH})_2$, suspended in H_2O , heated to 50° , let cool 2 hrs., filtered, salted out with Na_2SO_4 , dried, extd. from inorganic substances with abs. alc. and pptd. by Et_2O ; it seps. in dark flakes, which become bronze colored in the air. If, instead of adding Na_2SO_4 , the above soln. is carefully neutralized with KOH , the neutral sulfate (h), $[\text{C}(\text{C}_6\text{H}_4\text{CO}_2\text{H})(\text{C}_6\text{H}_4\text{NMe}_2)_2\text{C}_6\text{H}_4\text{NMe}_2]_2\text{SO}_4$, seps. as a grayish green powder, sol. in alc. and pptd. by Et_2O as a dark, bronze-colored solid. When (g) is decompd. by alkali in excess, (h) first seps., then $4^1,4^2$ -di[*dimethylamino*]- 4^2 -carboxytriphenylcarbinol (i), which then forms the sol. K salt. (i) is sepd. from (h) by soln. in alc., pptn. of (h) with Et_2O , filtering and cong., when (i) is obtained in colorless needles which become light green on exposure to the air, darken 230° , m. 268° ; the potassium salt seps. as a faintly yellow, opalescent mass from H_2O . The substitution of the CN and CO_2H groups in the *p*-position in malachite green produces the same gradation of color as has already been observed when NO_2 , SO_3H , Me, MeO and Cl are introduced; *o*-substitution produces a more blue-green, *m*- makes very little change, while *p*-substitution gives a more yellowish shade (*Ber.* 39, 2041). Both (e) and the salts of (i) dye mordanted wool and cotton a green color which is considerably more yellow than malachite green; the intensity of color is weaker than that of the mother substance. The *m*- CO_2H compd. has a still weaker intensity than either (e) or (i). (i) will dye wool without the use of a mordant.

NORMAN A. SHEPARD.

p-Chloro- and *p*-bromo-*m*-cresols. L. R. F. VON WALTHER AND W. ZIPPER. *J. prakt. Chem.* 91, 364-414 (1915).—Halogenated cresols have powerful antiseptic properties; *p*-chloro-*m*-cresol surpasses all other analogous phenol derivs. in this respect and therefore derivs. of this substance are of special interest. While the chlorination of *o*- and *p*-cresol with the formation of monosubstitution products proceeds with comparative ease (cf. *Ber.* 16, 1598), *m*-cresol shows a great tendency to take up 2 atoms of Cl and it is only by protecting the OH group or observing special precautions as to temp. and diln. that the formation of dichloro-*m*-cresol can be avoided. By chlorinating *m*- $\text{HOC}_6\text{H}_4\text{Me}$ (a) in glacial or 90% AcOH both at room temp. and at 100° , the following compds. were isolated by W. and Z.: 2,4,6-trichloro-*m*-cresol (b), 1-methyl-2,4,5-trichloroquinone dichloride (c), 1-chloromethyl-2,4,5-trichloroquinone dichloride (d), and 2,4,5-trichlorotoluquinone (e). (b) seps. in prisms when (a) in glacial AcOH is satd. cold with Cl; faintly yellow needles in clusters, m. 45° (cf. *C. A.* 6, 354; 7, 2546). When the filtrate from (b) is again satd. with Cl and allowed to stand, (d) seps.; prisms from alc., m. 117° . (e) is obtained when (a) is satd. at 100° with Cl. Some (d) seps. on cooling, which is filtered off, the soln. again satd. with Cl, cooled, and dild. with H_2O , when an oil seps. which deposits (e), yellow leaves from alc., m. 238° (decompn.). This m. p. is somewhat higher than that ascribed by previous investigators (cf. *Ann.* 168, 268; 172, 210; 237, 145) and lower than that of Michaelis (*Ann.* 293, 275). When (a) in the least quantity of 90% AcOH is satd. with Cl at 100° , a yellow oil and a cryst. solid sep. on cooling. The latter consists of (c), (d) and (e), which may be sepd. by crystn. from alc. 4,6-Dichloro-3-cresol (f), probably the dichloro-*m*-cresol obtained by Claus and Schweitzer (*Ber.* 19, 927) on chlorinating (a) hot and considered to be the 2,4- Cl_2 compd., was obtained by W. and Z. from 6-chloro-3-cresol (*p*-chloro-*m*-cresol) (g), when treated in warm aq. Na_2CO_3 with the calcd. quantity of Cl and allowed to stand. The yellow oil which seps. on diln. with H_2O is probably a mixt. of mono-, di- and trichloro-*m*-cresols; on long standing (f) crystals from this mixt., needles from Et_2O , m. 45 – 6° ; FeCl_3 gives no phenol reaction. Contrary to the finding of C. and S., neither this product nor any other dichloro-*m*-cresol was ever

obtained by W. and Z. by the direct chlorination of (a) in AcOH. *6-Bromo-3-cresol* (h) is obtained smoothly in 83% yield when (a) in CCl₄ is treated slowly with the calcd. amt. of Br at -5° to -10°; needles from H₂O or ligroin, volatile with steam, m. 62°; 100 cc. H₂O dissolves 0.1713 g. at 19°. *Benzoyl derivative*, from BzCl in C₆H₅N, needles from alc., m. 83-83.5°. *6-Chloro-4-bromo-3-cresol* (i) is obtained in needles when (g) in CCl₄ is treated with Br in CCl₄ in portions and the solvent evapd.; needles from petr. ether, m. 70-70.5°. When (g) in glacial AcOH is treated with Br until the red color persists, a brownish red oil seps., from which *6-chloro-2,4-dibromo-3-cresol* (j) is extd. by 50% AcOH; needles from petr. ether, m. 70°-70.5°, b₁₇ 177°; yield, 67%. *6-Chloro-3-hydroxy-4-toluic acid* (*p*-chloro-*m*-cresotinic acid) (k), previously prepd. by Gattermann (*Ber.* 26, 1851), is obtained in 95% yield when dry Na (g) is heated at 160-75° with an excess of CO₂ at high pressure for 6 hrs. The brown product is dissolved in NaOH, largely dild., decolorized hot with SnCl₂, filtered and pptd. by HCl; leaves from CHCl₃, needles from alc., m. 206-7°; it is volatile with steam and sublimes readily; 100 cc. H₂O dissolves 0.0120 g. at 12°. (The Na salt of (g) is much more readily decompd. than PhONa; in the presence of a trace of H₂O, it chars as low as 180°.) (k) is also formed in almost quant. yield by the action of Cl (calcd. amt.) on *m*-cresotinic acid (l) in glacial AcOH. (c), (d) and (e) are also formed in small quantities, but there was no tendency to form polyhalogenated cresotinic acids when AcOH, CCl₄, CHCl₃, C₆H₆ or Me₂CO were used as solvents. Alc., AcOEt, Et₂O, ligroin and CS₂ are not suitable mediums; H₂O leads to the formation of (e). *Sodium salt* of (k), seps. in leaves from 96% alc.; *potassium salt*, needles from H₂O; *lithium salt*, clusters of needles from alc.; *ammonium salt*, needles from alc.; *neutral calcium and neutral barium salts*, leaves from H₂O; *silver salt*, fine needles; *lead, mercury and aluminium salts*, all very difficultly sol.; *magnesium salt*, leaves from H₂O; *manganese salt*, bright violet needles from H₂O; *basic copper salt*, green leaves, insol. in H₂O; *bismuth salt*, very difficultly sol. With FeCl₃ (k) gives a violet coloration; when the chloride is in excess a brownish red ppt. seps. *Hexamethylenetetramine p-chloro-m-cresotinate*, (CH₂)₆N₄C₆H₇O₃Cl, prisms from alc., m. 170° (decompn.) and gives a weak blue fluorescence in aq. NaOH; *antipyrine salt*, C₈H₇O₃Cl.C₁₁H₁₃ON₃, needles from H₂O, m. 128°; *quinine salt*, C₈H₇O₃Cl.C₂₀H₂₁O₂N₃, an oil from H₂O, crystg. in indefinite form; *cinchonine salt*, C₈H₇O₃Cl.C₁₉H₂₁ON₃, indefinite crystals from H₂O. *Methyl ester* of (k), (m), leaves from MeOH, m. 55°; *ethyl ester* (n), faintly yellow leaves from 96% alc., m. 52-3°; *propyl ester* (o), prisms, m. 21°, b₁₈ 168-70°. *Methyl 2-methoxy-4-methyl-5-chlorobenzoate* (p), from the Na salt of (m) with EtI or from the Na salt of the (l) with Me₂SO₄ in NaOH soln., faintly yellow needles from MeOH, m. 53-4°, b₁₄ 160°. *Methyl 2-ethoxy-4-methyl-5-chlorobenzoate*, b₁₁ 170°; pptd. from MeOH by H₂O in faintly yellow needles, m. 54°. *Methyl 2-propyloxy-4-methyl-5-chlorobenzoate*, b₂₁ 188°. *Methyl 2-isopropyloxy-4-methyl-5-chlorobenzoate*, a highly refractive oil, b₁₉ 173°. *Methyl 2-butyloxy-4-methyl-5-chlorobenzoate*, faintly yellow refractive oil, b₂₀ 194°. *Methyl 2-isobutyloxy-4-methyl-5-chlorobenzoate* (q), refractive oil, crystg. in prisms, b₁₄ 187°. *Methyl 2-isoamyloxy-4-methyl-5-chlorobenzoate*, faintly yellow refractive oil, b₁₈ 197°. *2-Methoxy-4-methyl-5-chlorobenzoic acid*, obtained by sapon. of (p), prisms from alc., m. 130°; *sodium salt*, needles; the salts of the alkali metals and the ammonium salt are sol.; *calcium, barium, lead, silver, the yellow ferric and the blue copper salts* are all difficultly sol. *2-Ethoxy-4-methyl-5-chlorobenzoic acid* (r), needles from H₂O, m. 143°, *2-propyloxy-4-methyl-5-chlorobenzoic acid*, broad prisms from CCl₄, m. 112° (*sodium salt*, needles), *2-isopropyloxy-4-methyl-5-chlorobenzoic acid*, long prisms from ligroin, m. 121°, *2-butyloxy-4-methyl-5-chlorobenzoic acid*, needles from ligroin, m. 96.5°, and *2-isoamyloxy-4-methyl-5-chlorobenzoic acid*, leaves from ligroin, m. 94°. are all obtained by sapon. of the corresponding esters. Sapon. of (q) with alc. NaOH gave a mixt. of *2-isobutyloxy-4-methyl-5-chlorobenzoic acid* and (r), m. 117°, which

could not be sepd. 3-Methyl-4-chlorophenyl salicylate, $C_6H_4(OH)CO_2C_6H_4MeCl$, is formed when $o-HOC_6H_4CO_2H$ is heated at $135-40^\circ$ with (g) in the presence of $POCl_3$; fine needles from alc., m. 74° . 3-Methyl-4-chlorophenyl *p*-chloro-*m*-cresotinate, from (k), (g), and $POCl_3$ at 140° , small needles from MeOH, m. 142° . Phenyl *p*-chloro-*m*-cresotinate (s), needles from MeOH, m. 88° . β -Naphthyl *p*-chloro-*m*-cresotinate, prisms from Me_2CO , m. 137.5° . Sapon. of these new "salols" shows a behavior similar to $C_6H_4(OH)CO_2Ph$; their therapeutic application is thus possible. Acetyl-*p*-chloro-*m*-cresotinic acid, clusters of needles from CCl_4 , m. 146° . 5-Chloro-4-methyl-2-hydroxybenzoyl chloride (t) is easily obtained on heating (k) with $SOCl_2$ at 80° ; long needles from petr. ether, m. 48° ; it cannot be distd. without decompn. Treated with $PhOH$, (t) gives (s). The amide of (k), leaves from alc., is formed when (t) is treated in Et_2O with dry NH_3 ; anilide, leaves from alc., m. 222° ; *p*-phenetidine, from (t) and $p-NH_2-C_6H_4OEt$, leaves from 96% alc., m. 215° . 6-Bromo-3-hydroxy-4-toluic acid (*p*-bromo-*m*-cresotinic acid) (u) is obtained in theoretical yield when 106 g. Br in 300 g. CCl_4 is slowly dropped into 100 g. (l) in 1 kg. CCl_4 and let stand 24 hrs.; prisms from 96% alc., which give a bluish violet coloration with $FeCl_3$ and m. 221° (not 211° , as Gattermann, *Ber.* 26, 1851, gave it); ammonium salt, needles from H_2O ; the alkali, cobalt and magnesium salts are all easily sol. while the barium, silver, mercury, lead, gold, bright yellow platinum, brownish violet ferric and yellowish green copper salts are all difficultly sol. Both (k) and (u) are more powerful antiseptics than $o-HOC_6H_4CO_2H$. Methyl 2-methoxy-4-methyl-5-bromobenzoate, formed when (u) is treated with Me_2SO_4 and $MeONa$, seps. from dil. MeOH in leaves, m. $45-6^\circ$; the yield is small as the chief product is methyl 2-hydroxy-4-methyl-5-bromobenzoate, needles from MeOH, m. 48° . Acetyl-*p*-bromo-*m*-cresotinic acid seps. in leaves from $CHCl_3$, m. 155° . When (g) in 80% AcOH is treated cold with dil. HNO_3 , a yellow substance seps. from which 6-chloro-4-nitro-3-cresol (v) is obtained on crystn. from alc. in yellow leaves, m. 133.5° ; ammonium salt, orange yellow leaves from H_2O , m. 146° (decompn.); sodium salt, red needles; potassium and barium salts, red leaves; calcium salt, orange-red needles; mercury salt, brownish yellow leaves; copper salt, bright green leaves; lead salt, brick red; ferric salt, yellowish to dark brown, featherlike crystals; aluminium salt, yellow featherlike crystals; chromium salt, bright green; silver, gold, and platinum salts, yellow leaves; aniline salt, yellow leaves from alc., m. 134° ; *p*-toluidine salt, bright yellow leaves, m. 133° ; *o*-toluidine salt, yellow leaves, m. 132° . On evapg. the alc. mother liquors from (v), 6-chloro-2,4-dinitro-3-cresol (w) seps.; yellow leaves from ligroin, m. 69° . If heat is applied during the nitration of (g), (w) is the only product of the reaction. Ammonium salt, orange needles, m. $190-224^\circ$ (decompn.); sodium salt, orange; potassium salt, orange needles; calcium salt, golden yellow scales; barium salt, microscopic orange needles; mercury salt, reddish brown needles; copper and lead salts, brown needles; ferric and aluminium salts, brown leaves; chromium salt, leaves; silver, gold and platinum salts, yellow needles; aniline, *p*-toluidine and *o*-toluidine salts, orange needles, m. 136° , 145° and 78° , resp. Reduced with H_2SO_4 in boiling H_2O , (v) is converted into 6-chloro-4-amino-3-cresol, which seps. on cooling in leaves, m. 143° ; yield, 80%.

NORMAN A. SHEPARD.

Alcoholysis of esters. ANTONIO MADINAVEITIA. Madrid. *Anales soc. españ. fis. quim.* 12, 426-8(1914).—Willstätter observed that the alc. (phytol) produced in the alcoholysis of chlorophyll with EtOH did not remain free, but formed a mixed ether by reaction with EtOH. M. attempted to ascertain if this phenomenon is of frequent occurrence in the alcoholysis of esters. Methanolysis of castor oil was effected by boiling 150 g. castor oil for 9 hrs. with 450 cc. MeOH containing 3% HCl; the liquid was then poured into H_2O and the aq. layer was sepd., neutralized with NaOH and concd. to a small vol. Abs. alc. was added and the filtrate from the pptd. NaCl

was heated to remove alc. and then subjected to fractional distn. under reduced pressure; almost all the liquid b₁₆ 172-3°. This distillate was characterized by means of its product of benzoylation. The alcoholysis of almond oil, butter fat, triacetin and AcOPh was studied in the same manner and the ethanolysis of spermaceti, isomyl acetate and cyclohexanyl acetate was investigated by a similar procedure. The free alc. was obtained from the ester in each instance, so that the behavior of chlorophyll toward alcoholysis is an exception to the general rule. H. S. PAINE.

The preparation of sarcosine. LOUIS BAUMANN. State Univ. of Iowa. *J. Biol. Chem.* 21, 563-6(1915).—Dissolve 1 g. mol. of MeNH₂.HCl in 120 cc. of com. HCHO and add 1 g. mol. of KCN, dissolved in the least amt. of H₂O at 40°, until the temp. of the mixt. reaches 70°. Maintain that temp. by means of ice while adding the rest of the KCN. After 3 hrs., ext. the mixt. 5 times with Et₂O, dry with Na₂SO₄, filter and distil the Et₂O. Remove the last traces of Et₂O and some of the excess of the HCHO by blowing air into the flask. Suspend the residue in 400 cc. of H₂O containing 125 g. of Ba(OH)₂.8H₂O and sapon. the nitrile by boiling under reflux for 12 hrs. Add a little NH₄OH to the cold filtered soln. and remove the Ba with CO₂. Filter off the BaCO₃ with suction, wash and evap. the filtrate *in vacuo* to a thick sirup. Dissolve in the least amt. of boiling abs. alc. and place in a refrigerator for 24 hrs. Filter off the cryst. sarcosine with suction and wash with cold abs. alc. until nearly colorless. Yield, 25%. Prepare the MeNH₂.HCl according to the method of Brochet and Cambier (*Bull. soc. chim.* [3] 13, 533(1895)). *Sarcosine hydrochloride*, from sarcosine by evapn. with concd. alc. HCl and pptn. with Et₂O. *Methylureidoacetic acid*, obtained by heating sarcosine with an equal wt. of urea under reflux, m. 153° (uncor.). *Methylhydantoin*, from the ureido acid by boiling with 5 N HCl for 3 hrs. under reflux, m. 153° (uncor.). Treated with picric acid and 10% NaOH, it develops a color equal to 5% of that developed by creatinine. A. P. LOTHROP.

The abietic acids. P. POORH. *Farben-Ztg.* 20, 1056-9(1915).—A lengthy review of the literature is given, a consideration of which shows that the abietic acids are probably derivs. of retene or of a terpene. It is not possible to state which of these is more probably correct. The greater part of the published exptl. work supports the former view. E. W. BOUGHTON.

Physico-chemical study on the synthesis of chlorophyll. ALBERT MARY and ALEX. MARY. *Mon. sci.* [5] 5, 121-8(1915).—When strong HNO₃ is added drop by drop to strong alc. PhNH₂, there forms a white ppt. which quickly turns to a pale or bright rose color (leuco-aniline). An energetic reaction then sets in and a beautiful green soln. is produced: $6C_6H_7N + 15O = C_{24}H_{10}NO_4 + 6H_2O + 5NO$. A brown-red residue collects which yields a greenish fluorescent soln. when extd. with C₆H₆. This soln. on exposure to air gives a brownish resinous deposit. Evapn. of the C₆H₆ soln. yields needle-like plates of crystals joined in groups which are reddish or brownish by transmitted light and green by reflected light. One must work rapidly to stop the reaction when the green color develops. Synthetic chlorophyll, like the natural ext., is insol. in H₂O, sol. in alc., ether, petr. oil, and C₆H₆. Evapn. of the C₆H₆ soln. in both cases gives similarly cryst. bodies. The absorption spectrum of the synthetic product is the same as that of the natural chlorophyll—a max. in the red, a minimum in the less refrangible part of the visible spectrum and a 2nd max. in the violet. The spectrum of a C₆H₆ soln. of oxidized synthetic chlorophyll showed a minimum value in the red and changed progressively to a max. in the violet. A chlorophyll soln. (*Hedera helix*), when it was treated with Fe and AcOH for 4 hrs. and the Fe was removed with K₄Fe(CN)₆, gave a pale amber-yellow soln. The addition of a few drops of HNO₃ to this reduced soln. gave a green color while more acid caused the formation of a red-brown soln. These colors exactly sum up the stages in the formation and alteration of the synthetic

product. The pigments developed by bacterial chromogens in certain nitrogenous mixtures establish a connection between colored substances of the chlorophyll group and the aniline colors. The physical and optical properties of pigments developed by *S. cerevisiae* in an alc. soln. of aniline sulfate and cane sugar (1:20) and of *B. olearius fluorescens* in glycerol bouillon are identical. Fremy's reaction can be produced by freshly prepared synthetic chlorophyll thus: one adds 4 cc. C_6H_6 and 0.5 cc. $PhNH_2$ to 0.5 cc. HNO_3 and 4 cc. HCl and shakes gently. When a green color appears, one adds 2 cc. Et_2O and shakes, and the $Et_2O-C_6H_6$ layer is colored yellowish, while the acid is an intense greenish blue. The color changes rapidly to red-brown and at the end of 12 hrs., red-brown flakes are seen. A similar change is observed with natural chlorophyll ext. The soln. of synthetic chlorophyll in HCl has an absorption spectrum exactly comparable with that of *Polypodium vulgare*, of *Pinus sylvestris* and of *Viola tricolor*. The absorption begins in the red visible part of the spectrum. Chlorophyll solns. in alc., Et_2O or C_6H_6 showed an absorption spectrum whose bands vary between 715 and 700 μ . Confirmation of the theory of Willstätter (*Ann.* 1906, 48-82) that chlorophyll is a complex organomagnesium combination dissociated by acids, was not obtained, for, by vigorously shaking a C_6H_6 soln. of chlorophyll with an equal vol. of NH_4OH , upon sepn. of the liquids, the NH_4OH was almost opaque with a ppt. of $Mg(OH)_2$. This soln. was filtered and the process repeated 6 times to remove all the Mg . It was shown that the chlorophyll retained its characteristics and exists independently of Mg and its compds., for this soln. free from Mg showed an absorption spectrum identical with that of the original product.

R. L. SIBLEY.

Molecular transpositions in the α -glycols. S. A. KOOPAL. Univ. Leyden. *Rec. trav. chim.* 34, 115-78 (1915).—The transposition of α -glycols into aldehydes or ketones has long been known. In those in which a H atom is changed there has been agreement, but in those in which the C skeleton is changed the existence of the change has been contested or variously explained. Some have assumed the existence of intermediate compds.; Some denied them. The rules for detg. the product of the reaction of the α -acyclic glycols are: (1) *Sym. α -glycols* with 4 similar groups give only 1 transposition product. (2) In *sym. α -glycols* the transposition is detd. by the relative mobility of the groups. The order of mobility is thus: $4-MeC_6H_4 > 4-FC_6H_4 > Ph$ and $IC_4H_9 > 4-BrC_4H_9 > 4-ClC_4H_9 > H > Me >$ higher alkyls. (3) *Asym. α -glycols*: (a) In the primary-secondary aliphatic hydrocarbon group the OH groups change places with the H atom so that 2 products are formed simultaneously. In the primary-secondary aromatic group the primary OH changes place with the Ph group and the other OH with H. (b) In the primary-tertiary glycols the tertiary OH changes places with an H atom to give an aldehyde. (c) In the secondary-secondary glycols those having 2 different aliphatic hydrocarbon groups are unknown; in those having 1 aliphatic and 1 aromatic group the OH near the latter changes places with the H; those having 2 different aromatic groups are unknown. (d) In the pinacols $R'_2C(OH^a).C(OH^b)R_2$ the relative mobility of the OH's is important for when $R' = Ph$ and $R'' = Me$ or Et or when $R' = Me$ and $R'' = Et$ the OH changes its place. For the pinacols $R'_2C(OH)C(OH)R'R''$ only 2 are known and they are not regular in their behavior. The behavior of all known glycols in this respect is carefully reviewed under the proper headings. There are 5 of the type (1); 8 of the type (2); and 33 of the type (3). In concluding his review of the noncyclic asym. α -glycols of type (3) K. states that the relative mobility of the group bound to $>C(OH)C(OH)<$ is not the detg. principle for the direction of the reaction. By examples it was shown that the tertiary OH is more mobile than a secondary or primary OH, so that the tertiary OH always reacts. Whether a secondary OH group is more mobile than a primary OH cannot be detd. since (1)

both take place. When R is Me or Et the mechanism (1) is very probable. If (2) were true in this case the alkyl would have to be more mobile than the H. When R is Ph no choice can be made between (1) and (2). The bissecondary α -glycols $\text{ArHC}(\text{OH})\text{CHAlkOH} \longrightarrow \text{ArH}_2\text{CC}(\text{:O})\text{Alk}$ are rearranged in such a way that H and not Ph is transposed. The secondary OH group under the influence of Ph is more mobile than the other. In the cyclic α -glycols in which at least 1 OH is bound to C in the ring the relative mobility of the groups is not the only factor detg. the direction of the reaction. The greater or less possibility of a change of the ring is of great importance in this case as is shown from a number of examples. K. cites 12 reactions in which derivs. of α -glycols undergo intramol. transformations which are often interpreted as α -glycol transformations: glycerol $\longrightarrow$ acetol; formation of acrolein from glycerol; glyceric acid $\longrightarrow$ pyrotartaric acid; fermentation phenomena; hexoses $\longrightarrow$ levulinic acid. The purpose of K.'s expts. was to det. the influence of the character and of the place of halogen atoms on the pinacolic transposition in the disubstituted sym. halogenbenzopinacols. The following were prepd.: *sym.*-4,4'-diiodobenzopinacol (a) *sym.*-4,4'-difluorobenzopinacol (b), *sym.*-3,3'-dichlorobenzopinacol (c), *sym.*-3,3'-dibromobenzopinacol (d), *sym.*-2,2'-dichlorobenzopinacol (e), and *sym.*-2,2'-dibromobenzopinacol (f). All were prepd. by reduction of the corresponding ketones, which were obtained by Friedel and Crafts' method (halogenbenzoyl chloride + AlCl_3 + C_6H_6). The halogenbenzoyl chlorides were obtained from the acids. The reduction was done in 3 ways: (1) with EtOH in sunlight; (2) with EtOH in the light from a Hg lamp of Schott & Co., Jena; (3) with AcOH + Zn powder. The 3rd method is best because it is quicker and gives a better yield. Method (1) also gave good results but was slow. (2) was not efficient. All the pinacols treated with KOH + EtOH gave a bright blue color, which slowly disappears. The α - and β -pinacolins do not give this reaction. The transposition was studied thus: The pinacol was placed in a glass tube with AlCl_3 , the tube sealed and heated for some time at 100° . For the 4,4'-dihalogen derivs., of 100 mols., (a) Ph was transposed in 50 mols. and $\text{C}_6\text{H}_4\text{I}$ in 50 mols.; in 100 mols. (b) Ph and $\text{C}_6\text{H}_4\text{F}$ were transposed in 35 and 65 mols., resp.; in 100 mols. of the 4,4'-Cl₂ compd., 60 mols. Ph and 40 mols. $\text{C}_6\text{H}_4\text{Cl}$, resp., were transposed; in 100 mols. of the 4,4'-Br₂ deriv. 57-8 mols. Ph and 42-3 mols. $\text{C}_6\text{H}_4\text{Br}$ were transposed. The products in each case were $\text{XC}_6\text{H}_4(\text{Ph})_2\text{CC}(\text{:O})\text{C}_6\text{H}_4\text{X}$ and $(\text{XC}_6\text{H}_4)_2\text{PhCC}(\text{:O})\text{Ph}$, resp., in which X = halogen. Thus the introduction of F in the *p*-position increases the mobility of the Ph, and with Cl and Br it diminishes it; I has no effect. In (b) the substituted Ph is more mobile than the Ph. In (c) and (d) only 1 product is formed: only 3- $\text{C}_6\text{H}_4\text{X}$ is transposed, so that here Ph is much less mobile than 3- $\text{C}_6\text{H}_4\text{X}$. The same result was obtained for (e) and (f). With the *o*-substituted pinacols transposition is very slow, while with the *m*- and *p*-derivs. it is complete after 7 hrs. and with 1.5 parts by wt. of AlCl_3 . The *o*-derivs. were heated 64 hrs. with 12.5 parts of AlCl_3 . The hydrolysis of the product with EtOH + KOH gave a Ph_2CH deriv. and a halobenzoic acid but was always very slow. *Methods of analysis:* In the direct method the products of the reaction were 1st purified either by crystn. or distn. and then used for the detn. of the constitution. Most transpositions have been studied in this way. But usually it is difficult and sometimes impossible to sep. the products quant. This method was used for (c), (d), (e) and (f). The indirect method consists in treating the product with EtOH + KOH and analyzing the mixt. of benzoic acids obtained. A test expt. showed that the hydrolysis is quant. The halobenzoic acid in the mixt. could be sep. and

dried according to the method of Montagne (*C. A.* 1, 2887; 4, 1485). After hydrolysis is complete H_2O is added and the $EtOH$ evapd. off; the Ph_3CH derivs. are removed by filtration and the soln. dild. until only the halobenzoic acid is pptd. on acidifying with HCl . This method can be used only when but 1 group is transposed or when the difference in solubility is sufficient. The acids may also be analyzed by detg. the halogen according to Baubigny and Chavanne (*Compt. rend.* 138, 85). The alk. hydrolysis mixt. was nearly neutralized with H_2SO_4 and evapd. to dryness in a small flask, cooled and treated with concd. H_2SO_4 and $K_2Cr_2O_7$ and the Cl or Br evolved detd. as usual. When mixed crystals are formed as with $p\text{-}FC_6H_4CO_2H + BzOH$ the comp. of the mixt. was detd. by the m. p. from the m. p. curve for this system. *Prepn. of halobenzoic acids:* In each case the corresponding toluidine was converted into the halotoluene and then into the halobenzoic acid. Details and numerical results are given. $2\text{-}NH_2\text{-}C_6H_4Me$ by Sandmeyer's reaction gave $2\text{-}ClC_6H_4Me$ which on oxidizing with dil. $KMnO_4$ gave $2\text{-}ClC_6H_4CO_2H$, m. 140° ; it was also obtained from $2\text{-}NH_2C_6H_4CO_2H$. $3\text{-}ClC_6H_4CO_2H$, m. 157.5° , and 2- and $3\text{-}BrC_6H_4CO_2H$ were obtained similarly. The method of Wheeler and McFarland (*Am. Chem. J.* 19, 364) for brominating $BzOH$ was found to be the best method for obtaining $3\text{-}BrC_6H_4CO_2H$, but other products were also sepd. The crude product was poured into H_2O and the Fe sepd. with $NaOH$. During filtration some oil passed through the filter and solidified (probably C_6Br_6). Steam distn. gave a colorless oil which was sepd. by distn. into 4 fractions from which $m\text{-}C_6H_4Br_3$, $p\text{-}C_6H_4Br_2$ and $1,2,4,5\text{-}C_6H_2Br_4$ were sepd. The alk. soln. treated with HCl pptd. $3\text{-}BrC_6H_4CO_2H$ and from the $EtOH$ mother liquor some $3,4\text{-}Br_2C_6H_3CO_2H$, m. 232° , was isolated. In brominating $BzOH$ in a closed vessel according to Angerstein and fractionally pptg. the acids from KOH with HCl , pure $3\text{-}BrC_6H_4CO_2H$ was easily obtained and $3,4\text{-}$ and $3,6\text{-}Br_2C_6H_3CO_2H$ were isolated. $6,3\text{-}Br(O_2N)C_6H_3CO_2H$ (Holleman, *Rec. trav. chim.* 20, 206) was reduced to the NH_2 deriv. with $Sn + HCl$ and 4 g. of the latter with 24 g. 48% $HBr + 1.4$ g. $NaNO_2$ in 40 cc. $H_2O +$ "Naturkupper C" gave $3,6\text{-}Br_2C_6H_3CO_2H$. In prep. $2,3\text{-}Br_2C_6H_3CO_2H$ similarly the NH_2 was substituted with Br by the method used by Holleman in getting $2\text{-}BrC_6H_4CO_2H$ from $2\text{-}NH_2C_6H_4CO_2H$. The prepn. of $3,4\text{-}Br_2C_6H_3CO_2H$ was similar to that for the $3,6\text{-}$ deriv. $4\text{-}NH_2C_6H_4CO_2H$ was brominated in HCl with $Br\text{-}H_2O$ (Beilstein, Geitner, *Ann.* 139, 1; *Ber.* 27, 513). The $3,5,4\text{-}Br_3(NH_2)C_6H_2CO_2H$ obtained is sol. in org. solvents, m. 330° (decompn.). A mixt. of 21 g. + 6 g. KNO_3 was added gradually to HNO_3 (d. 1.40), then poured into H_2O , treated with Na_2CO_3 to neutralize 90% of the acid, heated on the H_2O bath with a few cc. of $CuSO_4$ soln. + 40 cc. $EtOH$: the $3,5\text{-}Br_2C_6H_3CO_2H$, m. 219° , sepd. $4\text{-}IC_6H_4CO_2H$ and $4\text{-}FC_6H_4CO_2H$ were obtained from 4-toluidine. *Prepn. of the monohalobenzophenones:* The chlorides of the halobenzoic acids were prepd. from the acids by treating them with the calcd. amt. of PCl_5 and fractional distn. In the case of $4\text{-}IC_6H_4COCl$ the $POCl_3$ was distd. off and the residue crystd. from petr. ether. $4\text{-}FC_6H_4COCl$ was partly volatilized unchanged when boiled with KOH . 2- and 3- chloro-, 2- and 3- bromo- and 4- iodobenzophenones were obtained by heating the corresponding halogen acid chloride + $C_6H_6 + AlCl_3 + CS_2$. Willgerodt and Bogel (*Ber.* 38, 3452) found that $BzCl + PhI + AlCl_3$ give $4\text{-}IC_6H_4Bz$. K. got variable results with this method. It was best to heat 14 g. $BzCl + 40$ g. $PhI + 13$ g. $AlCl_3$ at 60° for 2 days in the sunlight (yield, 25 g.). In the synthesis of $p\text{-}$ halobenzophenones by this method the $o\text{-}$ deriv. is usually obtained as is shown by the formation of phenylindoxazene by the action of alk. NH_2OH on the $o\text{-}$ deriv. This was found for $2\text{-}IC_6H_4Bz$ by Wachter (*Ber.* 26, 1745) and verified by K. by the following syntheses: $2\text{-}NH_2C_6H_4CO_2H \longrightarrow 2\text{-}IC_6H_4CO_2H \longrightarrow 2\text{-}IC_6H_4COCl \longrightarrow 2\text{-}IC_6H_4Bz$ which with NH_2OH gives the phenylindoxazene. The solns. from the prepn. of the $4\text{-}IC_6H_4Bz$ above failed to give this reaction. $4\text{-}FC_6H_4Bz$ was also obtained by the Friedel-Crafts' reaction. *Prepn. of the benzopinacols, etc.:* (1) 35 g. $2\text{-}ClC_6H_4Bz$ (g), in 105 cc. $EtOH$

exposed some days in a uvioI tube, gave a white ppt. and much unchanged (g). Exposed again, more white ppt. seps. The yield of (e) (cf. above) was good. (2) The EtOH soln. of (g) treated with ultraviolet rays gave a poor yield of (e). (3) The results of reducing (g) with Zn + AcOH (C. A. 1, 2887) are rapid and good. 2-Chlorobenzhydrol, $C_{12}H_{11}OCl$, obtained by reducing (g) in EtOH with 10% Na-Hg, needles, m. 65° , sol. in org. solvents. The results for the 3 methods of reduction of 3- ClC_6H_4Bz for the prepn. of (c) were about the same. (c) m. $137-8^\circ$, crystals with difficulty and is sol. in org. solvents. 3-Chlorobenzhydrol, from the 3-Cl isomer with 10% Na-Hg, m. 40° , sol. in org. solvents except petr. ether. For the prepn. of (f) methods (1) and (2) failed but (3) gave a good result; (f) m. 168° , sol. in C_6H_6 , less sol. in petr. ether and EtOH. 2-Bromobenzhydrol, obtained like the Cl deriv., m. 56° . In the prepn. of (d) methods (1) and (3) were successful. (d) seps. as minute needle conglomerates, m. 147° , sol. in org. solvents. The reduction of 3- BrC_6H_4Bz with Na-Hg gave an oil which did not crystallize in several months. (a) could not be prepd. by method (1) since the 4- IC_6H_4Bz decomposed and $\frac{3}{4}$ of the I was liberated as HI. Method (3) gave a good yield of (a). (a) seps. as minute needles, m. $171-2^\circ$, sol. in C_6H_6 , little sol. in petr. ether. The reduction of 4- FC_6H_4Bz by method (1) to give (b) gave nearly the theoretical yield in 1.5 months' exposure. Both methods (2) and (3) also gave good yields of (b). (b) seps. as small plates, m. 176.5° . 4-Fluorobenzhydrol, m. 48° , is sol. in C_6H_6 and EtOH. The intramolecular transposition of the halogenpinacols, etc.: The general results obtained in these transpositions were discussed above. For exptl. details cf. the original. By the transposition of (e) with $AcCl$ at 100° for 64 hrs. the β -pinacolin, 1,1-diphenyl-1,2-di-[2-chlorophenyl] ethanone, $ClC_6H_4(Ph)_2CCOC_6H_4Cl$, m. 140° , was obtained. Similarly (e) gave the 1,2-di-[3-chlorophenyl] compound, m. 105° ; from (f) the 1,2-di-[2-bromophenyl] compound was obtained; (d) gave the 1,3-di-[3-bromophenyl] compound, m. 115° . The results with the sym.-4,4'-dihalogen derivs. are given above.

E. J. WITZEMANN.

Some heterocyclic organo-silicon compounds. ARTUR BYGDÉN. Stockholm. Ber. 48, 1236-42 (1915).—To 10 g. Mg shavings, a speck of I and 200 cc. almost abs. Et_2O kept below the b. p. is slowly added 30 g. $CH_2(CH_2CH_2Br)_2$, and after standing overnight the mixt. is boiled 4 hrs. and siphoned from the 4.4 g. Mg remaining undissolved; the Grignard reagent so prepd., dild. with 200 cc. Et_2O and cooled with ice, is treated with 20 g. $SiCl_4$, boiled 6 hrs., most of the Et_2O distd. off, the distillate poured back upon the residue and filtered (protected from moisture) from the insol. salts; the combined filtrates from 2 expts. on fractionation yield 1.5, 21.6, 4.0 and 1.2 g. fractions b. $167.5-9^\circ$, $169.0-72^\circ$, $172-90^\circ$, $>190^\circ$, resp., and leave a dark brown residue converted by treatment with dil. HCl and H_2O into about 4 g. of a dirty yellow product; the fraction b. $>190^\circ$ also yielded an insol. solid on standing in moist air. A fraction of the main product, $b_m 169.5-70.5^\circ$, $d_4^{20} 1.1779$, $d_4^{30.1} 1.1668$, $d_4^{40.0} 1.1560$, $d_4^{50.1} 1.1453$, $n 1.46700$, 1.46973 , 1.47634 , 1.48191 for α , D , β and γ at 20.2° , had the comp. of cyclopentamethylenesilicon dichloride, $CH_2CH_2CH_2CH_2CH_2SiCl_2$ (a); it is a clear liquid

of penetrating odor, burning with a bright green-rimmed flame and sepn. of SiO_2 and hydrolyzed by H_2O to a viscous mass, sol. in all proportions in the ordinary org. solvents; the residue from the Et_2O soln. on drying at high temps. first gelatinizes and then gradually shrinks to hard yellow-brown pieces, at the same time losing wt. and evolving a peculiar odor; dried at 110° , it loses 2.4% in wt. at 205° and contains 24.35% Si; it is probably a polymeric cyclopentamethylenesilicone, $(C_5H_{10}SiO)_n$. From the Grignard reagent from MeBr and 8.3 Mg in 300 cc. cold Et_2O , treated slowly with 23.2 g. (a) in 75 cc. Et_2O , then boiled 6 hrs., freed from most of the Et_2O which was then poured back upon the residue, treated with 1% H_2SO_4 to dissolve the salts, and the Et_2O layer

then drawn off, dried with Na_2SO_4 and fractioned, are obtained (1) 10.2 g. b. $<155^\circ$, and (2) 5.0 g. b. $>155^\circ$. (1) vigorously shaken 3 times with concd. H_2SO_4 (to which it imparted a yellow color) left undissolved 8.4 g. sepd. into 0.6, 5.8 and 1.0 g. fractions b. $128.5\text{--}32.5^\circ$, $132.5\text{--}4.0^\circ$, $>134^\circ$, resp.; from the middle portion was isolated *dimethylcyclopentamethylenesilicane*, $\text{C}_5\text{H}_{11}\text{SiMe}_2$, b_{780} , $133\text{--}4^\circ$, d_4^{20} 0.8210, $d_4^{10.6}$ 0.8120, $d_4^{20.0}$ 0.8039, $d_4^{29.8}$ 0.7955, n_D^{20} 1.43684, 1.43940, 1.44575, 1.45100; it is an easily inflammable liquid with a faint camphor-like odor. The H_2SO_4 with which (1) had been shaken when poured into cold H_2O deposited 1.7 g. of a yellow oil which did not boil const. No definite product could be isolated from (2), the b. p. rising continuously from 140° to 275° under 15 mm., only about 0.5 of the product distg. over; this fraction and the residue were viscous, almost wholly insol. in H_2SO_4 and had an unpleasant odor. From the Grignard reagent from 24 g. $\text{CH}_2(\text{CH}_2\text{CH}_2\text{Br})_2$ treated with 11 g. Et_2SiCl_2 is obtained 6.4 g. oil insol. in H_2SO_4 , the main portion of which (2 g.) b. $184\text{--}94^\circ$ and has approx. the comp. of *diethylcyclopentamethylenesilicane*. CHAS. A. ROULLIER.

1,2-Aminophenyl mercaptan. TH. ZINCKE AND G. SIEBERT. Marburg. *Ber.* 48, 1242-54 (1915).—*o*-Aminophenyl methyl sulfide (a), from 20 g. of the NO_2 compd. and 40 g. Zn dust treated on the H_2O bath with 140 cc. crude HCl , first drop by drop and then in larger amts., and then heated with occasional additions of Zn dust until the soln. is clear, liquid of faint C_{10}H_8 -like odor, b_{18} , $133\text{--}4^\circ$, stable for a long time (even in the light), when pure, gives no dye but only a dirty brown color with FeCl_3 . *Hydrochloride*, long, silky needles. *Formyl derivative*, obtained by boiling with 95% HCO_2H , prisms from C_6H_6 -benzine, m. $53\text{--}4^\circ$. *Acetyl derivative*, obtained with Ac_2O and NaOAc , leaflets from alc., m. $102\text{--}3^\circ$. *Benzoyl derivative*, spears from alc., m. 96° . Heated a long time with equimol. amts. of $2,4\text{-(O}_2\text{N)}_2\text{C}_6\text{H}_3\text{Cl}$ and KOAc in alc., (a) gives the compound $(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{NHC}_6\text{H}_4\text{SMe}$, dark orange-red needles from AcOH , m. $158\text{--}66^\circ$, which with boiling alc. Na_2S gives the *2-amino compound*, $2,4\text{-H}_2\text{N(O}_2\text{N)}_2\text{C}_6\text{H}_3\text{NHC}_6\text{H}_4\text{SMe}$, dark garnet-red crystals from alc., m. 137° ; this with HNO_3 forms an azimido deriv. *o*-Iodophenyl methyl sulfide, from (a) through the diazo compd. and KI , light yellow oil, b_{20} 173° ; with excess of H_2O_2 in AcOH after several hrs. on the H_2O bath it gives the *sulfone*, needles from alc., m. $106\text{--}7^\circ$. *o*-Methylmercaptobenzonitrile, from (a) by the Sandmeyer reaction, faintly yellow, felted needles from MeOH , m. $40\text{--}1^\circ$, hydrolyzed by boiling aq. alc. KOH to the acid, needles from dil. alc., m. 169° (Friedländer, *Ann.* 351, 401 (1907), gives 164°). *o*-Aminophenyl methyl sulfoxide, strongly refractive oil whose *hydrochloride*, needles from alc., m. 167° , turning deep blue; the sulfoxide is obtained by hydrolysis with alc. KOH of its *acetyl derivative*, m. $114\text{--}5^\circ$, which is prepd. from 5 g. $\text{AcNHC}_6\text{H}_4\text{SMe}$ in 12 cc. AcOH and 4 cc. of 30% H_2O_2 after 12 hrs. at room temp. *Sulfone*, leaflets from dil. alc., m. $65\text{--}6^\circ$, obtained by boiling with alc. HCl its *acetyl derivative*, m. $139\text{--}40^\circ$, which is prepd. from 2 g. $\text{AcNHC}_6\text{H}_4\text{SMe}$ in 10 cc. AcOH heated 2 hrs. on the H_2O bath with excess of 30% H_2O_2 ; *benzoyl derivative*, made in the same way, needles from MeOH , m. $118\text{--}9^\circ$. From $\text{BzNHC}_6\text{H}_4\text{SMe}$ in 7.5 parts cold AcOH satd. with Cl and allowed to stand 24 hrs. is obtained the *benzoyl derivative*, silky needles from MeOH , m. $138\text{--}9^\circ$, of *5-chloro-2-aminophenyl methyl sulfoxide*, quadratic leaflets from dil. alc., m. $120\text{--}1^\circ$. The Bz deriv. with H_2O_2 in AcOH gives the *sulfone* (also obtained from $\text{BzNHC}_6\text{H}_4\text{SO}_2\text{Me}$ and Cl in AcOH), needles from MeOH , m. $159\text{--}60^\circ$. With 1 part Br in 1 part AcOH , on the other hand, $\text{AcNH-C}_6\text{H}_4\text{SMe}$ gives *3,5-dibromo-2-acetaminophenyl methyl sulfide* (b), needles from AcOH , m. $162\text{--}3^\circ$. *2-Benzoylamino analog* (c), m. $122\text{--}3^\circ$. Slowly heated with 4-5 parts POCl_3 to 130° and kept at this temp. for 2 hrs., the Ac and Bz derivs. of (a) lose MeOH with formation of methyl- and phenylbenzthiazole, resp. The sulfoxides undergo reduction, $\text{AcNHC}_6\text{H}_4\text{SOME}$ giving methylbenzthiazole. *Methylidibromobenzthiazole*, from (b), needles from alc., m. $120\text{--}1^\circ$; *phenyl analog*, from (c), needles from dil. AcOH ,

becoming granular on standing, m. $168-9^{\circ}$. From 1 g. (a)-HCl heated 2 hrs. at 130° with 6 cc. of 95% HCO_2H and 4 cc. POCl_3 is obtained *benzosulfazole*, $\text{C}_6\text{H}_4\text{N}:\text{CH}.\text{SO}_2$.

leaflets from dil. alc., m. $105-7^{\circ}$. *Methylbenzosulfazole*, obtained in the same way from $\text{AcNHC}_6\text{H}_4\text{SO}_2\text{Me}$, leaflets, m. $149-50^{\circ}$. *Phenyl analog*, from $\text{BzNHC}_6\text{H}_4\text{SO}_2\text{Me}$, cryst. powder, m. $169-70^{\circ}$. [2-Methylmercaptophenyl]trimethylammonium iodide, from (a) and MeI heated 6 hrs. in MeOH on the H_2O bath in sealed tubes, prisms from H_2O , m. $162-3^{\circ}$ with loss of MeI, forms with 1 part I in MeOH a diiodide, $\text{C}_{10}\text{H}_{12}\text{NSI}_2$, apparently monoclinic leaves from MeOH, violet in incident, brown in transmitted light, while with 2 parts I is obtained a *tetraiodide*, blue-black needles. The iodide heated *in vacuo* at $170-5^{\circ}$, or 12-5 hrs. at 180° with 5 parts MeOH satd. with HCl, gives *o*-dimethylaminophenyl methyl sulfide, oil smelling like PhNMe_2 , b₇₆₀ 130° , does not form a NO compd.; *hydrochloride*, hygroscopic, deliquescent needles.

CHAS. A. ROULLIER.

Catalytic actions of colloidal metals of the platinum group. XIV. Stepwise reduction of acetylene with colloidal platinum. C. PAAL AND ANTON SCHWARZ. Univ. Erlangen. *Ber.* 48, 1202-7(1915); cf. C. A. 9, 1184, 1883, 2380.—Colloidal Pt preps. containing, besides Na protalbate, 50-59% Pt in the solid state were used in the P. and Gerum shaking app. In 1 expt. the H was gradually introduced into the shaking arm containing the C_2H_2 ; in the other expts. the 2 gases (equal vols. of each) were previously mixed. Some of the expts. were carried out under atm. pressure at room temp., others under a slight excess of pressure at $50-60^{\circ}$. Comparison of the results with those obtained with Pd hydrosol shows that with Pt the reduction proceeds considerably more slowly, and while with Pd the reduction can be so regulated that practically only C_2H_4 and no C_2H_6 are formed, in the expts. thus far carried out with Pt 35-40% C_2H_6 is formed.

CHAS. A. ROULLIER.

Some β -substitution derivatives of butyric acid containing sulfur. J. M. LOVÉN AND HJALMAR JOHANSSON. Univ. Lund. *Ber.* 48, 1254-62(1915).— $\text{MeCHClCH}_2\text{CO}_2\text{H}$ (a), b₁₆ 108° , is obtained in 35.5 g. yield from 26 g. $\text{MeCH}:\text{CHCO}_2\text{H}$ heated 2 hrs. at $70-80^{\circ}$ with 50-5 cc. HCl satd. with HCl gas in the cold, opened, again satd. with HCl in the cold and heated 4 hrs. at 100° ; with HCl in alc. it gives the Et ester, b₁₆ $65-5.5^{\circ}$. $\text{MeCHBrCH}_2\text{CO}_2\text{H}$ (b), b₁₆ $117.5-8.5^{\circ}$, is obtained in 115 g. yield from 65 g. $\text{MeCH}:\text{CHCO}_2\text{H}$ allowed to stand 1 day with 50 cc. HBr satd. in the cold with HBr gas, the satn. and standing being repeated twice more. Either (a) or (b), exactly neutralized with crystd. soda in 0.5 its wt. of H_2O at about 35° , then treated with the equiv. amt. of EtOCS_2K , allowed to stand 24 hrs. and treated with HCl gives the impure, oily β -xanthobutyric acid which, treated in concd. K_2CO_3 soln. with 1.5 times the calcd. amt. of concd. NH_3 , allowed to stand 24 hrs., freed from EtOCSNH_2 with Et_4O , and of NH_3 on the H_2O bath, acidified with H_2SO_4 and extd. with Et_4O gives the crude $\text{MeCH}(\text{SH})\text{CH}_2\text{CO}_2\text{H}$; this is supersatd. with NH_3 after the addition of a few drops of FeCl_3 , allowed to stand several days exposed to the air in a flat dish and filtered; HCl ppts. a mixt. of *dl*- and *meso*- β -bisulfidibutyric acids, $(\text{HO}_2\text{CCH}_2\text{CHMeS})_2$ (yield, 20% starting from (a) or 55% from (b)), cannot be sepd. by crystn. from H_2O , but this is effected through the Ba salts; 20 g. of the acids, exactly neutralized with about 200 cc. $\text{Ba}(\text{OH})_2$ and allowed to evap. at room temp., first deposit about 10 g. homogeneous thick, clear tables and then opaque, spherical aggregates, turning partially glassy on drying. The acid regenerated from the tables seps. from H_2O in leaves, m. 117° , sol. in about 300 parts cold H_2O ; *potassium salt*, small needles with 1 H_2O , deliquesces in moist air; *barium salt*, tables or pyramids with 2 H_2O , weathers in dry air, sol. in about 20 parts H_2O at room temp. Attempts to resolve the acid into active components with *l*-phenethylamine failed. When the mother liquors

from the above well-crystd. Ba salt are treated with dil. HCl and the recrystd. ppt. is treated in acetone with 2-4 vols. H_2O there is obtained the 2nd form of the acid in silvery scales, m. $117-9^\circ$, depresses the m. p. of the other acid; *potassium salt*, deliquescent, usually being obtained as an efflorescence but sometimes in flat needles; *barium salt*, spherical aggregates. β -Sulfidodibutyric acid, best obtained (15 g. yield) as the Ba salt from 75 g. $MeCHBrCH_2CO_2Et$ treated 3 days on the H_2O bath with somewhat more than the equiv. amt. of alc. KSH, neutralized with HCl, treated with $BaCl_2$ and warmed, prisms, m. $84-5^\circ$, sol. in 2 parts H_2O at room temp.; *barium salt*, granular ppt. The filtrate from the Ba salt is acidified with HCl, extd. with Et_2O , evapd., freed of $MeCH:CHCO_2H$ with steam, again extd. with Et_2O , neutralized with $Ba(OH)_2$ and warmed (whereby more of the above Ba salt is pptd.), filtered, treated with $CaCl_2$ and warmed; this gives a granular salt from which is obtained a 2nd form of the acid, lancet-shaped crystals from CCl_4 , m. $62-4^\circ$, sol. in about $1/3$ part H_2O . The 1st acid, neutralized with soda and treated with $KMnO_4$, as long as the latter is rapidly decolorized, gives β -sulfodibutyric acid, $(HO_2CCH_2CHMe)_2SO_4$, rhombic tables, m. $169.5-71^\circ$; *potassium salt*, glassy mass becoming moist in the air; *barium salt*, glassy mass stable in the air; *acid potassium salt*, leafy crusts. CHAS. A. ROUILLER.

β -Butyrolactone. HJALMAR JOHANSSON. Univ. Lund. *Ber.* 48, 1262-6(1915); cf. C. A. 6, 1316; Holmberg, C. A. 8, 1576.—Just as with the monobromosuccinic acids, so the conversion of $MeCHBrCH_2CO_2Na$ into $NaBr + MeCH(OH)CH_2CO_2H$ in neutral soln. is a reaction of the 1st order and the Br ion concn. increases much more rapidly than the acidity, a phenomenon most easily explained by the assumption of the formation of a β -lactone, $MeCH.CH_2.CO.O$, as the 1st stage of the reaction. This

β -butyrolactone was isolated by neutralizing the acid with soda at $40-5^\circ$, cooling to room temp. every 0.5 hr., extg. with Et_2O , drying with $CaCl_2$ and evapg. The residues thus obtained from 14 g. acid when distd. under 29 mm. gave 0.5 g. b. $71-2^\circ$ and 0.9 g. b. $72-4^\circ$; the latter fraction, a mobile refractive liquid of acetone-like odor, contains 55.83% C (calcd., 55.78%) and neutralizes 23.03 cc. $Ba(OH)_2$ (calcd., 23.04 cc.). The velocity coeff. of hydrolysis in H_2O (1st order reaction) slowly decreases with time, being $8.5, 8.3, 8.2 \times 10^{-4}$ after 360, 1070, 1830 min., resp., for 5 cc. of 0.1367 *N* lactone soln. + 8.67 cc. H_2O at 25° . The alk. hydrolysis seems to be a reaction of the 2nd order, independent of the nature of the cation, the velocity coeff. for initial concns. 0.005 of lactone and NaOH or $Ba(OH)_2$ being 50. C. A. R.

Desmotropism of derivatives of succinylsuccinic ester. HUGO KAUFFMANN. *Ber.* 48, 1267-72(1915).—The chrome-yellow product obtained by Baeyer from succinylsuccinic ester (a) and NH_3 (*Ber.* 19, 429(1886)) has been found to be merely an impure form of the colorless compd. obtained by Liebermann (C. A. 8, 2150); no colored forms exist and the supposed desmotropism of (a) is erroneous. K. leaves open the question as to which of the 2 formulas proposed for the supposed desmotropes is the correct one. The colored impurity formed in the action of NH_3 and primary amines is probably isomorphous with the main products, for it cannot be removed by crystn. or with charcoal; its formation can be avoided by carefully excluding atm. O, and it is therefore nothing but the corresponding diaminoterephthalic ester (b). To obtain the compd. colorless, the $AcONH_4$ (prepd. from NH_3 and $AcOH$) is 1st boiled in H and the (a) in boiled $CHCl_3$ is dropped into the resolidified $AcONH_4$ and the $CHCl_3$ allowed to evap. in H, then the residue is heated until the yellow oil dissolves in the melted $AcONH_4$ and the solidified melt treated in a current of H with 80 cc. of boiled H_2O ; even under these conditions the product is still slightly colored (probably owing to traces of O in the H); 1 g. is therefore gently boiled 0.5 hr. in H in 30 cc. alc. and 5 cc. *N* KOH and treated with 150 cc. boiled H_2O , quickly filtered, washed

with boiled H_2O and crystd. in H from $MeOH$ previously boiled in H . The white needles so obtained m. 178° . By the final treatment the colored impurity is converted into alkali salts of the hydrolysis products of (b); the aq. alk. filtrate (which is almost colorless) gives a deeply colored material on acidification and extn. with Et_2O ; both H_2SO_4 in large excess and alkalis remove it from the Et_2O . The crystd. colorless product is quite stable when dry and dissolves without color in solvents previously boiled in H but in the air the solns. soon become yellowish and fluorescent; the same differences are observed when the solid is fused in H or in air. With (a) and $PhNH_2$, carefully excluding O as above, a colorless product is again obtained and dissolves without color or fluorescence, but when melted in the air becomes intensely orange-red; colored preps. can be decolorized by cautious treatment with alc. KOH . C. A. R.

Neutral salt compounds of the amino acids and polypeptides. P. PFEIFFER AND FR. WITTKA. Univ. Zurich. *Ber.* 48, 1289-310(1915); cf. C. A. 7, 3764.—It has already been pointed out that the compds. formed by NH_2 acids with neutral salts cannot be metal ammonias of the type $X_mM(\dots NH_2CH_2CO_2H)_m$, for the betaines, in which the N is coordinately satd., also combine with neutral salts. It has now been found that sarcosine, which stands between glycocoll and betaine, forms with neutral salts compds. which, in comp. and appearance, correspond in some cases to the glycocoll, in others to the betaine compds., so that there can be no doubt as to the close relationship of all these series of compds. The metal atom of the neutral salt must therefore be bound to the O of the NH_2 acid. The "amphi salt" theory previously proposed, however, does not agree with the discovery, which has now been made, of the existence of the compds. $MX_4MeNHCH_2CO_2H_4H_2O$ ($MX = KBr, KI, RbBr$), $CaCl_2(NH_2CH_2CO_2)_2Cu_3H_2O$, $CaCl_2R_2H_2O$, $2LiCl.R_2.5H_2O$, $2LiBr.R_2.5H_2O$ ($R =$ diacipiperazine), and $CaCl_2.3R_9H_2O$ and $2CaCl_2.3R_{12}H_2O$ ($R =$ antipyrine). These must therefore be mol. compds. and the simplest assumption is that the metal atoms of the inorganic salt are coordinately bound to the carbonyl O of the org. component; e. g., $ClLi\dots O:C.CH_2.NH_2O$, $ClLi(\dots O:C.CH_2.NH_2O)_2$, etc. It is not

impossible that these simple formulas may in certain cases be slightly different in that the negative residue occupies a position different from that indicated above; e. g.,

mol. compds. of alkali and alk. earths salts are not exceptional is shown by a long list of some of the compds. which these salts form with alcs. or phenols, sugars, acids, anhydrides, esters, amides, alkylsulfonates and amines. [In the following formulas $a = NH_2$ acid, $s =$ metallic salt.] Triglycocoll-calcium chloride, $3a.s.$, has now been prepd. from 0.5 g. a and 4 g. $s.6H_2O$ in 10 cc. of H_2O at 30° treated with 70 cc. alc. and allowed to stand 24 hrs., whereupon tables of $3a.s$ sep.; in only 1 expt. did the needles of $2a.s.4H_2O$ sep. instead of $3a.s$. Copper glycocoll-calcium chloride. $a.s.3H_2O$ ($a = (NH_2CH_2CO_2)_2Cu$), from 0.5 g. a and 2.5 g. $s.6H_2O$ in a little H_2O allowed to cryst. at room temp., deep blue transparent tables, slowly weathers in the air to a light blue powder, decomps. on heating before it loses all of its H_2O , loses 1 H_2O over P_2O_5 ; if less than 2.5 g. $s.6H_2O$ is used, there seps. a mixt. of the blue needles of a and the blue tables above. Dibetaine-barium bromide, $2a.s.6H_2O$, from 0.9 g. s and 1.1 g. a in a little H_2O allowed to evap. over $CaCl_2$ at room temp., leaflets, attracts moisture from the air, decomps. on heating before losing all of its H_2O , loses 2.5 H_2O over P_2O_5 . Betaine-copper chloride, $a.s.3H_2O$, from 1 g. green s and 0.5 g. a in 4.8 cc. H_2O treated with 80 cc. alc., yellow-green radiating needles, does not lose H_2O over P_2O_5 or at 100° , m.

about 183° , evolves NMe_3 on a Pt foil, forms a turbid bluish liquid with a little H_2O , insol. in and unchanged by boiling alc. In its prepn. there first seps. a brownish yellow powder which redissolves on standing; this is extraordinarily deliquescent in the air but is indefinitely stable over P_2O_5 ; it dissolves turbid in H_2O with bluish color and analysis indicates that it is anhydrous *a.s.* contaminated with basic salt (found, Cu 25.91, Cl 25.24, 25.30%). *Sarcosine-calcium chloride*, *a.s.* $4\text{H}_2\text{O}$, from an aq. soln. of equimol. amts. of *a* and *s* allowed to evap. spontaneously, transparent needles becoming anhydrous on heating. *Trisarcosine-calcium chloride*, *3a.s.*, from a filtered soln. of *s* and 2-3 mols. *a* concd. on the H_2O bath, transparent tables; if only 2 mols. *a* is used, the mother liquors also deposit fine needles of *a.s.* $4\text{H}_2\text{O}$. *Sarcosine-strontium chloride*, *a.s.* $4\text{H}_2\text{O}$, asbestos-like needles. *Sarcosine-barium chloride*, *a.s.* $4\text{H}_2\text{O}$, needles. *Sarcosine-barium bromide*, *a.s.* $4\text{H}_2\text{O}$, needles. *Disarcosine-magnesium chloride*, *2a.s.* $2\text{H}_2\text{O}$, leaflets from 1.8 g. *a* and 2 g. $5.6\text{H}_2\text{O}$ allowed to evap. at room temp. *Sarcosine-sodium iodide*, *a.s.* H_2O , from a soln. of 1 mol. *s* and 2 mols. *a* concd. on the H_2O bath, rhombic plates, deliquesces in the air. *Tetrasarcosine-potassium bromide*, *4a.s.* $4\text{H}_2\text{O}$, from *s* and 3-4 mols. *a*, silky needles, deliquesces in the air. *Tetrasarcosine-potassium iodide*, *4a.s.* $4\text{H}_2\text{O}$, felted needles. *Tetrasarcosine-rubidium bromide*, *4a.s.* $4\text{H}_2\text{O}$, silky, felted needles. *Disarcosine hydrobromide*, *2a.s.* (*s* = HBr), hygroscopic needles which can be recrystd. from a little H_2O , obtained by evapg. over CaCl_2 a soln. containing 1-1.5 mols. (*a*) and the normal salt, *a.s.* flat, broad needles, which is prepd. by concg. *a* in excess of aq. HBr . *Diacypiperasine-calcium chloride*, *a.s.* $2\text{H}_2\text{O}$, seps. from a warm soln. of 1 g. *a* and 10 g. $5.6\text{H}_2\text{O}$ on cooling in thick, transparent prisms, weathers without melting on heating; a hot aq. soln. on cooling deposits *a*. *Diacypiperasine-dilithium chloride*, *a.2s.2.5H}_2\text{O}, from 1 g. *a* and 8-10 g. *s* evapd. on the H_2O bath, transparent needles, does not melt, weathers on heating and then carbonizes, converted by a little H_2O into a white powder; on clay in the air it goes over into *a* in the course of 24 hrs. *Diacypiperasine-dilithium bromide*, *a.2s.2.5H}_2\text{O}, transparent needles, forms a white powder with a little H_2O , softens but does not melt on heating, is converted into *a* in the air. *Triantipyrrine-calcium chloride*, *3a.s.* $9\text{H}_2\text{O}$, from aq. solns. of *a* and *s* allowed to evap. at room temp., needles. *Triantipyrrine-dicalcium chloride*, *3a.2s.12H}_2\text{O}, silky needles from a hot concd. aq. soln. of *a* and a large excess of *s* quickly cooled; if the crystn. is slow a mixt. of the 3:2 and 3:1 compds. seps., and if not at least 4 g. $5.6\text{H}_2\text{O}$ per g. *a* is used a mixt. of the 3:2 compd. and *a* is deposited. *Diantipyrrine-copper chloride*, *2a.s.*, from 1 g. *a* and 2 g. $5.2\text{H}_2\text{O}$, brown needles, m. $160-1^{\circ}$, forms a turbid yellow-green soln. in hot alc. and on short standing deposits a white ppt.; it is sol. in H_2O with blue color.***

CHAS. A. ROUILLER.

Catalytic hydrogenation. I. New method of hydrogenation of volatile substances and the rate of hydrogenation of ethylene. J. B. RATHER AND E. EMMET REID. *J. Am. Chem. Soc.* 37, 2115-8 (1915); cf. *C. A.* 9, 2609, for the app. used.—The volatile substance to be hydrogenated, mixed with H_2 , is passed through a nonvolatile liquid containing the catalyst and kept thoroughly stirred. The catalyst used for the study of the reduction of C_2H_4 was prepd. by treating 100 g. infusorial earth with 50 g. $\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ in 150 cc. H_2O , adding the resulting moist mass to a concd. soln. of 60 g. $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$, washing, drying, reducing below red heat in H_2 until no more H_2O was formed and cooling in CO_2 ; 1.0 g. of this reduced the I no. of 70 g. cottonseed oil from 113.7 to 44.6 after 60 min. treatment in the hydrogenation app. at 180° , and its activity did not deteriorate appreciably during the period each portion of it was in use. The $\text{C}_2\text{H}_4 + \text{H}_2$ (10-50% C_2H_4) was passed at the rate of 10-200 cc. per min. into a mixt. of 1 g. catalyst + 70 g. paraffin kept at $180 \pm 1^{\circ}$, the stirrer being run at the rate of 3300-3500 revolutions per min., and the amt. of C_2H_4 in the issuing gases was detd. when equil. was reached. For all mixts. of $\text{C}_2\text{H}_4 + \text{H}_2$ studied, about 70%

of the C_2H_4 is reduced when the rate of flow is 10 cc. per min. All the results for the 10% mixts. are regular, while mixts. richer in C_2H_4 gave irregular results, the detg. factor doubtless being solubility and the reaction probably taking place between the gases dissolved in the paraffin. When the gas flow is rapid, the gases are carried through before equil. can be established between the gas mixt. and the soln. Plotting the vol. of gases combined per min. against the rate of flow showed, as was to be expected, that the vol. combined increased with the amt. of the gas mixt. exposed to the catalyst. In the 50% mixt. 17 cc. H_2 combined with 17 cc. C_2H_4 in 1 min., and since the 1 g. of catalyst cannot contain more than 0.1 g. or 0.01 cc. or less of Ni, the latter can bring about the combination of 3400 times its vol. (calcd. for 0°) of the gas mixt. in 1 min.

CHAS. A. ROUILLER.

The tolyl esters and toluidides of the nitrosulfonic acids of *p*-xylene. RALPH C. HUSRON. *J. Am. Chem. Soc.* 37, 2119-22(1915).—(All m. ps. are cor.) The tolyl esters of the 3 acids (*C. A.* 8, 2697, 3793) were prepd. from 0.75 g. cresol, 1 g. C_6H_5N and 1.75 g. chloride of the acid heated 15 min. at 90° and allowed to stand overnight. The toluidides were obtained from 1.5 g. acid chloride in 20 cc. CCl_4 treated with 2 cc. toluidine and évapd. on the H_2O bath. *o*-Tolyl 3-nitro-2,5-dimethylbenzenesulfonate, opaque, flat, pointed crystals from alc., m. $66-7^\circ$; *m*-tolyl ester, rhombohedral plates, m. $71.5-2.0^\circ$; *p*-tolyl ester, thin plates, m. $93.5-4.5^\circ$; *o*-toluidide, plates from 95% fine, flat needles from 50% alc., m. $126.5-7.5^\circ$; *p*-toluidide, silky filaments from 50% alc., m. $135-6^\circ$. *o*-Tolyl 6-nitro-2,5-dimethylbenzenesulfonate, opaque prisms, m. $151.5-2.0^\circ$; *m*-tolyl ester, plates, m. $107.5-8.0^\circ$; *p*-tolyl ester, needle-like plates, m. $76-7^\circ$; *o*-toluidide, rhombohedral plates, m. $143.5-5.0^\circ$; *p*-toluidide, flat needles, m. $158.5-9.0^\circ$. *o*-Tolyl 4-nitro-2,5-dimethylbenzenesulfonate, flat, opaque needles, m. $99-100^\circ$; *m*-tolyl ester, flat needles, m. $110-1^\circ$; *p*-tolyl ester, needle-like plates, m. $117.5-8.5^\circ$; *o*-toluidide, slightly yellow plates, m. $140.5-1.0^\circ$; *p*-toluidide, elongated plates, m. $143.5-4.5^\circ$. The m. ps. of the esters of the 3- and 4- NO_2 acids follow the rule of sym. $o < m < p$, while for those of the 6- NO_2 acid the order is $o > m > p$, a fact especially peculiar in the light of Smiles' theory (*Relations between Chemical Constitution and Some Physical Properties*, p. 208). For each acid, the solubility of its derivs. in org. solvents decreases with increasing m. p. As a rule, the derivs. of the 4- NO_2 acid are less sol. than their isomers.

CHAS. A. ROUILLER.

Comparative behavior of thiourea and urea towards acetic anhydride. EDWARD F. KOHMANN. *J. Am. Chem. Soc.* 37, 2130-3(1915).—In an attempt to prep. $AcNHCSNH_2$, 1.8 g. $CS(NH_2)_2$ was heated 1 hr. at 100° with 5 cc. Ac_2O ; on cooling yellow prisms sepd. which, after crystn. from H_2O , alc. or glacial $AcOH$, m. $150-5^\circ$ and contained 19.5% N; 0.5 g. of this product, heated 1 hr. at 100° in 10 cc. H_2O , gave colorless prisms of $AcNHCSNH_2$, m. 165° (N, 23.5%), while 0.5 g. of the original product, heated 1 hr. at 100° in 5 cc. Ac_2O , gave pale yellow, blade-like prisms of *diacetylthiourea*, m. $151-2^\circ$ (N, 17.4%), becomes bright lemon-yellow when heated at 110° and seps. from a concd. Ac_2O soln. in the same lemon-yellow form. Urea under the above conditions yields only the mono-Ac deriv.

CHAS. A. ROUILLER.

Hydantoins. XXXIII. Condensation of cinnamic aldehyde with hydantoins. TREAT B. JOHNSON AND RICHARD WRENSHALL. *J. Am. Chem. Soc.* 37, 2133-44(1915).—4-Cinnamylhydantoin (*a*), obtained in 72% yield from 10 g. hydantoin, 14 g. $PhCH:CHCHO$, 50 g. $NaOAc$ and 50 cc. $AcOH$ heated 6 hrs. at $130-40^\circ$, canary-yellow prisms from $AcOH$, stout or slender prisms (depending on the concn. and temp.) from 95% alc., m. $272-3^\circ$ (decompn.); 8.5 g. in 2.5 g. KOH and 360 cc. H_2O at $50-65^\circ$ slowly treated with 110 g. of 3% $Na-Hg$ and heated 1.5 hrs. gives 7 g. of γ -phenylpropenylhydantoinic acid, diamond-shaped plates from H_2O , m. $142-61^\circ$ (decompn.) depending on the rate of heating; 7 g. digested 50 hrs. with 50 g. $Ba(OH)_2$ in 20 cc. H_2O yields α -amino-

δ-phenyl-*β*-pentenic acid, needles from H₂O, m. 247-8° (some decompn.), sol. in about 100 parts boiling H₂O, converted by boiling 25% HCl in 1 hr. into 4-[*γ*-phenylpropenyl]-hydantoin, needles from 95% alc., m. 160-1°, while 2 g. of the acid heated 1 hr. at 100° with 2 g. NH₄CNS and 10 cc. Ac₂O gave 2.5 g. of 2-thio-3-acetyl-4-[*γ*-phenylpropenyl]-hydantoin, orange plates from 80% alc., m. 97-8°, converted by repeated evapns. with concd. HCl into 2-thio-4-[*γ*-phenylpropenyl]hydantoin (b), needles or distorted prisms from dil. alc., m. 126-7°, which, heated 4 hrs. at 140° with 10% CH₂ClCO₂H, gives 4-[*γ*-phenylpropenyl]hydantoin, needles, m. 160°. 2-Thio-4-cinnamalthydantoin (c), in 85% yield from 8 g. 2-thiohydantoin, 40 g. NaOAc and 60 cc. AcOH heated 2 hrs. at 130°, seps. from hot AcOH in red prismatic columns but below 70° in slender yellow needles; the red form m. 262-3°, while the yellow form first reddens 140-60° and contains 1 mol. AcOH of crystn. With Na-Hg it gives the gummy *γ*-phenylpropenylthiohydantoinic acid, converted by repeated evapn. with HCl into (b). 2-Thio-4-[*γ*-phenylpropenyl]hydantoin(?), quant. obtained from 2.5 g. (c) in enough AcOH to dissolve it at 65° heated 1.5 hrs. at 65-75° with 20 g. Zn dust, powder very sol. in org. solvents, begins to contract 175°, forms a red gum 185°, becomes partly fluid 190°, immediately decolorizes dil. KMnO₄ in acetone. Desulfurization of (c) requires 6 hrs. heating in a bomb tube with 4 mols. of 33% CH₂ClCO₂H. 4-[*α*-Bromocinnamal]-hydantoin, from 1.5 g. (a) in 200 cc. AcOH at 50-60° treated with the calcd. amt. of Br vapors, yellow needles, m. 290-5° (decompn.) depending on the rate of heating, also formed with excess of Br (4 mols.), there being no tendency for the Br to add to the allyl double bond. 4-[*β*-Bromocinnamal]hydantoin, obtained in 6 g. yield from 10 g. PhCH:CHBrCHO, 5 g. hydantoin, 25 g. NaOAc, 20 cc. AcOH and 20 cc. Ac₂O after 1.5 hrs. at 130°, yellow prisms from AcOH, m. 226-7° (decompn.), always decomp. to some extent when recrystd. 3-Acetyl-4-cinnamalthydantoin, from 1.5 g. (a) heated 4 hrs. at 140-50° with 30 cc. Ac₂O, yellow prisms from AcOH, m. 241-2°, easily hydrolyzed to (a) by hot HCl, also obtained in excellent yield from 3-acetylhydantoin, PhCH:CHCHO, NaOAc, AcOH and Ac₂O after 3.5 hrs. at 130-5°. CHAS. A. ROUILLER.

Pyrimidines. LXXV. Pyrimidine-aldehydes and their biochemical interest (thiouracilaldehyde). TREAT B. JOHNSON AND LEONARD H. CRETCHER, JR. *J. Am. Chem. Soc.* 37, 2144-51 (1915).—In connection with J.'s pyrimidine-nucleoside investigations it became necessary to obtain uracil (or thiouracil) combinations containing in position 4 a grouping, like CHO, which would make possible the synthesis, indirectly, of glycol and higher alc. combinations. The CHCl₃CO₂H used, b. 188-92°, was obtained in 76-87% yield from its K salt suspended in C₆H₆ decompd. with dry HCl, filtered from the KCl and freed from C₆H₆ by heating, finally at 150°; 105 g. of this is slowly dropped into 56.2 g. Na in 800 cc. alc. (distd. from Na) at 80°, cooled, treated below 10° with 35 g. HCl in abs. alc., allowed to stand 15-8 hrs. at room temp., exactly neutralized in the cold with alc. NaOEt, filtered from the NaCl, evapd. *in vacuo* at 30-5°, dild. with 20 cc. H₂O and a large vol. of Et₂O and the immiscible oil repeatedly extd. with Et₂O until its vol. remains const. (55 cc.); the Et₂O exts., after drying with Na₂SO₄, yielded 48 g. (EtO)₂CHCO₂Et (a), b₁₈ 94.5-8.0°, 10 g. b₂₀₋₁ 98-103°, and 12 g. of a higher fraction with indefinite b. p. The immiscible oil above, when cautiously acidified with HCl and extd. with Et₂O, yielded 48 g. (EtO)₂CHCO₂H which, on esterification with alc. HCl, gave 12 g. more of pure (a), b₁₈ 83-5°. From (a) was prepd., by a slight modification of Dakin and Dudley's method (*C. A.* 9, 201), (EtO)₂CHCO₂CH₂CO₂Et, 65 g. of which, heated 7 hrs. with 10.5 g. Na, 40 g. CS(NH₂)₂ and 250 cc. alc., freed from alc. at 100°, digested with charcoal in 275 cc. H₂O, cooled and cautiously acidified with dil. HCl, gave 52 g. 2-thio-4-uracilaldehyde diethylacetal (b), thick, rhombic blocks from 95% alc., m. 160°, is not desulfurized by digestion with alc. HgO, freshly pptd. Pb(OH)₂ or CH₂ClCO₂H, quant. hydrolyzed by heating to boiling with dil.

HCl to the free *aldehyde*, golden yellow plates with 1 H₂O, darkens about 230°, decomps. 250°, reduces NH₄-AgNO₃ and Fehling soln., seps. from its aq. soln. or on addition of H₂O to the AcOH soln. as a tar; *phenylhydrazone*, yellow needles, does not m. 300°. *2-Ethylmercapto-6-oxy-4-aldehydopyrimidine diethylacetal* (c), in 11 g. yield from 10 g. (b), 1 g. Na, 1.2 g. EtBr and 250 cc. alc. 1 hr. on the H₂O bath, slender needles from H₂O, m. 128°; free *aldehyde*, elongated prisms, m. 145°. *2-Methylmercapto acetal*, obtained practically quant. from (b), Na and MeI, needles from alc., m. 133°. *Uracil-4-aldehyde*, from (c) boiled 0.5 hr. with HCl, distorted prisms with 1 H₂O from dil. HCl, does not m. 300°. **LXXVI. New methods of synthesizing 2-ketopyrimidines and their sulfur analogs.** TREAT B. JOHNSON AND A. WILLARD JOYCE. *Ibid* 21, 51-64.—2,6-Dioxy-5-ethoxypyrimidine (*J. Biol. Chem.* 2, 441(1906)) is obtained in 90% yield from 50 g. 2-ethylmercapto-5-ethoxy-6-oxypyrimidine digested 6 hrs. with 58 g. CH₂ClCO₂H in 200 cc. H₂O; with excess of POCl₃ it gives 85% of 2-ethylmercapto-5-ethoxy-6-chloropyrimidine (a), while 34 g. heated 3 hrs. at 120-30° with 140 g. POCl₃ gives 90% of 2,6-dichloro-5-ethoxypyrimidine (b), m. 51°, not 41°, as previously given. (a) is not smoothly desulfurized by CH₂ClCO₂H, while 10 g. (a), 25 g. Zn dust, 75 cc. H₂O and 75 cc. of 95% alc. boiled 3 hrs. give 71% of 2-ethylmercapto-5-ethoxypyrimidine (c), thin plates or prisms from petr. ether, m. 31-2°, sol. in acids, repptd. by alkalis, mol. wt. in freezing C₆H₆ 180-2, forms a stable, easily hydrolyzed HCl salt; the aq. reaction mixt., after extrn. of the (c) with Et₂O and addition of sufficient NaOH to redissolve the Zn(OH)₂, leaves 0.6 g. cryst. ppt. sepg. from dil. alc. in needles, insol. in alkalis, m. 126-7°, mol. wt. in freezing C₆H₆ 202-4°. *Hydrochloride* of (c), prisms from (c) in Et₂O satd. with HCl, m. 120-1°; *chloroplatinate*, golden yellow prisms, m. 165-6°. (c) is not attacked by CH₂ClCO₂H after 18 hrs. heating, by Zn dust in boiling 50% alc. after 1 hr. or by satd. alc. NH₃ after 24 hrs. at 100°, 10 hrs. at 130-50°, 4 hrs. at 140-60°, and finally 10 hrs. more at 175-85°. (b) boiled 1.5 hrs. with 2 parts Zn dust in 50% alc. gives 80% of 2-chloro-5-ethoxypyrimidine, sol. in acids, insol. in alkalis, seps. from dil. alc. in thin plates, m. 70°, produces a cooling sensation on the tongue and in small amts. has a sweet taste; 6 g. heated 5 hrs. on the H₂O bath with 8.4 g. KOH in 60 cc. of 95% alc. satd. with H₂S gives 5 g. of 2-thio-5-ethoxypyrimidine (d), yellow columns from 20 parts AcOH, m. 192-3°, insol. in HCl, forms sulfides with hot basic Pb acetate or HgO, sol. in alkalis; the AcOH mother liquors on diln. with H₂O deposit a small amt. of the *sulfide* R₂S or R₂S₂ (R = N:CH.C(OEt):CH.N:C—), m.

125°, insol. in acids and alkalis; the N content agrees with that calcd. for the disulfide (17.90%; found, 17.87, 18.01). From 2.5 g. (d) in 1 g. KOH and 75 cc. alc. heated 3 hrs. with 15 g. EtBr is obtained (c), thus showing that it is the 6-Cl atom which is removed in the reduction of (b). Boiled 5 hrs. with 2 g. CH₂ClCO₂H in 50 cc. H₂O, 2.8 g. (d) gives 2.5 g. 5-ethoxypyrimidine-2-thioglycolic acid, needles, m. 137-8°, sol. in alkalis, insol. in acids, unchanged by boiling 4 hrs. with 10% alc. but decompd. with formation of tarry products on digesting 3.5 hrs. with concd. HCl. *2,5-Diethoxypyrimidine*, from the 2-chloro-5-ethoxypyrimidine and the calcd. amt. of alc. NaOEt, plates, m. 19°, b₄₄ 142°, insol. in alkalis, sol. in concd. acids; *hydrochloride*, needles, easily hydrolyzed; *chloroplatinate*, golden yellow prisms, m. 176° (decompn.). *2-Ethylmercapto-5-ethoxypyrimidine*, obtained in 75% yield from the 6-Cl compd. with Zn dust in 50% alc. boiled 1 hr., b₄₀ 115°, has an unpleasant pungent odor, gradually darkens in the air, sol. in concd. acids, insol. in alkalis; *hydrochloride*, m. 98-9°, unstable in damp air, dissociating into the base and HCl; *chloroplatinate*, golden yellow needles, m. 166°. The base, digested 5.5 hrs. with concd. HCl, gives 2-oxypyrimidine *hydrochloride*, m. 203-5°; *hydrobromide*; free base, light yellow, amorphous, does not m. 320°, possesses both basic and acid properties, is more sol. in NH₄Cl and NH₄Br than in H₂O. *2-Ethylmercapto-4-methylpyrimidine*, in 72% yield from the 6-Cl compd.

with Zn dust boiled 2.5 hrs. in 50% alc., b_{18-9} 123-4°, has a pungent odor, insol. in alkalis; *hydrochloride*, prisms, m. 141-2°, dissociated by H_2O ; *chloroplatinate*, needles, m. 165-6°. The above method of converting monochloropyrimidines into their corresponding EtS deriv. affords a valuable method of detg. the constitution of the former.

CHAS. A. ROULLER.

Nitrated proteins. II. Synthesis of 3,5-dinitrotyrosine. TREAT B. JOHNSON AND EDWARD F. KOHMANN. *J. Am. Chem. Soc.* 37, 2164-70(1915); cf. *C. A.* 9, 2529.—J. and K. have been unable to obtain a dinitrotyrosine by Städeler's method (*Ann.* 116, 82(1860); cf. also Thudicum and Wanklyn, *J. Chem. Soc.* 22, 283(1869)) with HNO_3 alone, only mononitrotyrosine and $(CO_2H)_2$ being obtained, the latter exclusively if the treatment was vigorous, but on the other hand the desired object is easily attained with a mixt. of HNO_3 and H_2SO_4 ; the resulting compd. differs in many respects from that described by S., and he must have had some other substance or, more probably, impure mono- NO_2 compd. The NO_2 groups enter the *o*-positions to the HO group. Like other di-*o*-substituted tyrosines, the compd. does not give the Millon test, indicating that the production of the red color in the test does not involve nitration. To 22 g. concd. H_2SO_4 and 3 g. concd. HNO_3 below 10° is slowly added 2 g. tyrosine and the mixt. is at once poured into H_2O ; in the combined solns. from 6 expts. the H_2SO_4 is quant. pptd. as $BaSO_4$, the Ba-free filtrate made distinctly alk. with NH_3 , evapd. to dryness *in vacuo* at 60°, treated with 25 cc. cold H_2O , decompd. with a little dil. HCl and extd. with boiling H_2O and charcoal; on cooling, 6 g. 3,5-dinitrotyrosine (a) seps. in golden yellow plates with 1 H_2O , becomes anhydrous and brick-red 140-50°, decomp. 220-30°; a hot satd. aq. soln. added to an equal vol. of boiling Millon soln. immediately gives a yellow ppt. of the salt $C_8H_5O_7N_2HgNO_3$, begins to decomp. 170°, effervesces 185°; from an HCl soln. of (a) concd. HCl ppts. the *hydrochloride*, bright yellow plates, begins to darken 220°, decomp. 230°. *Ammonium salt*, from (a) and concd. NH_3 , red prisms, decomp. above 230°. *Thiohydantoin*, $CO.NH.CS.NH.CH-$

$CH_2C_6H_3(NO_2)_2OH$, in 4 g. yield from 3.7 g. (a) heated 1 hr. on the H_2O bath with NH_4CNS and Ac_2O , poured into cold H_2O , filtered, suspended in strong HCl and evapd. to dryness, short prisms from 50% AcOH, m. 225-30° (decompn.); 4 g. heated 6 hrs. at 140° with 15 g. CH_2ClCO_2H and 45 cc. H_2O gives 2.9 g. 4-[3,5-dinitro-4-hydroxybenzyl]hydantoin, golden yellow blocks from AcOH, decomp. 235°, converted by Sn and warm dil. HCl and subsequent diazotization and treatment with Cu_2Cl_2 into the 3,5- Cl_2 compd. (Wheeler, J. and Hoffmann, *J. Biol. Chem.* 10, 147(1911)).

III. Conversion of fibroin into nitrofibroin (fibroin-xanthoproteic acid). TREAT B. JOHNSON, ARTHUR J. HILL AND LEON P. O'HARA. *Ibid* 2170-8; cf. Inouye, *C. A.* 7, 802.—The fibroin was prepd. by boiling 1 lb. of exceptionally pure silk noils with 15 l. of neutral 1% red oil soap for 6 hrs., thoroughly washing with warm and cold H_2O , drying at 100° and placing over H_2SO_4 . To obtain consistent results, the natural condition of the fiber must be preserved as much as possible, pure spun silk or silk yarn of close texture giving results entirely different from those obtained with the noils. To 20 g. portions of the noils in tall beakers was added 1 l. of HNO_3 (d. 1.12), the nitration allowed to proceed at room temp. (18-25°) with frequent stirring of the silk suspension, the product filtered at the end of a given period, washed repeatedly by maceration with cold H_2O until the washings gave no acid reaction, dried at 100°, weighed and analyzed for N. The yield of nitrofibroin ranged from 19.9608 g. with 17.90-17.92% after 12 hrs. to 12.0000 g. with 18.05-18.10% N after 552 hrs. nitration. Up to 48 hrs. the N increases to 18.8% but after 72 hrs. becomes const. around 18%. The yield falls continuously to about 14.3% after 196 hrs. and then remains practically const. for the next 240 hrs., the parallelism in yield and % N indicating a definite nitration product. The nitrofibroin obtained after 240 hrs., when placed in fresh

HNO₃ (d. 1.12) for another 13 days, suffered only a comparatively small change in wt. and no change in N content. When first placed in the acid, the noids did not change in appearance; in about 15 min. they became yellow in spots which rapidly diffused through the individual fibers as the action continued; after 12 hrs. the entire mass was a uniform golden yellow but the fibers did not lose their identity until several hrs. more; after 90 hrs., their disintegration began; the material was then deep golden yellow and could easily be pulverized when dry, by rubbing with the hand; further action produced only a powder of nitrated protein; after 240 and 552 hrs., resp., the products were a deep golden yellow, pulverulent material very much like mosaic gold, without cryst. structure. Up to 44 hrs., the products responded to the Millon test, the intensity of the color diminishing, however, with the length of nitration; beyond 24 hrs. neither the solid nor the filtrate gave the test. The nitrofibroin is insol. in NH₃, aq. alkali carbonates, 1% NaOH, 10% NaOH (changes from yellow to red, becoming more intense on heating; the alk. solns. assume a light orange color destroyed by acids), 50% NaOH (the soln. becomes orange, however, and colorless when neutralized or made slightly acid) and glacial AcOH, sol. in concd. acids (HCl, H₂SO₄, HNO₃), turns brown about 240°, almost black 300°, insol. in Schweitzer reagent, does not give the biuret reaction on account of the orange color of the alk. soln., sol. in hot 50% KOH with slight evolution of NH₃.

CHAS. A. ROUILLER.

Separation of the mono- β -, 2,6- and 2,7-sulfonic acids of anthraquinone. M. L. CROSSLEY. *J. Am. Chem. Soc.* 37, 2178-81(1915).—In the usual method of sepn. through the Ca salts, a considerable amt. of the β - and 2,6-salts is pptd. out and lost with the CaSO₄. C. has found the Na salts a better means of sepn.; 50 g. anthraquinone + 18 g. concd. H₂SO₄ mixed to a uniform paste are heated 2 hrs. at 170° in a covered casserole with 82 g. fuming H₂SO₄ (60% SO₃), boiled 0.5 hr. with 1 l. H₂O, filtered hot, almost neutralized with concd. NaOH, evapd. to a thick paste and pumped dry; the solid is a mixt. of the β - and 2,6-salts, sepd. by fractional crystn. from H₂O. The 2,6-salt changes in sunlight from a light plum color to almost black in sunlight. The filtrate is treated with 95% alc. till no more Na₂SO₄ is pptd., the filtrate evapd. almost to dryness and the residue, in a very little distd. H₂O, treated with a large excess of 95% alc. which ppts. a salmon-pink substance sol. in distd. H₂O with golden yellow color changing to pink on addition of a little tap H₂O and again changing to golden yellow on exposure to sunlight for 24 hrs.; tap H₂O again restores the color, but if the exposure to sunlight is repeated 2-3 times, the yellow color becomes permanent; addition of a drop of dil. NaOH to the pink soln. and exposure to sunlight produces a permanent ruby-red; the substance is a sensitive indicator (reddish pink in alk., golden yellow in acid soln.); the pink color is not discharged by CO₂. The compd. is practically insol. in most org. solvents, slightly in MeOH, changed by CHCl₃ to a dark red oil solidifying to red needles; with PhMe is also formed a dark red oil forming rods. Suspended in 95% alc. and exposed to sunlight it changes to a dark green substance which, when dry, slowly reverts to the salmon pink form and seems to be a loose addition product of the latter. The filtrate from the salmon pink compd. is again evapd. to dryness; the residue is the 2,6-salt. Yield, 2, 60, 28 and 9 g. of the β -, 2,6- and 2,7-salts and the new compd., resp. The best yield (38 g.) of β -salt ("silver salt"), which seps. best in faintly acid soln., is obtained by heating 50 g. anthraquinone + 9 g. H₂SO₄ with 41 g. fuming acid 2 hrs. at 160° and treating as above, the almost neutral soln. being evapd. to 1/2 its vol., whereupon the β -salt seps.

CHAS. A. ROUILLER.

Neutral ammonium salts of some substituted benzoic acids. V. LEROY McMASTER AND I. H. GODLOVE. *J. Am. Chem. Soc.* 37, 2181-8(1915); cf. C. A. 8, 3424. —The following neutral ammonium salts have been prepd. from the acids and dry NH₃ in anhydrous solvents: *m*- and *p*-toluates, *o*-, *m*- and *p*-chloro-, bromo-, nitro- and amino-

and 3,5-dinitrobenzoates. All can be prepd. in Et_2O . The toluates are cryst. ppts. sol. in H_2O , acetone and AcOH , stable in dry air, slowly give off NH_3 in moist air, form neutral aq. solns.; the *m*- and *p*-salts are slightly deliquescent. Of the chlorobenzoates, the *p*-salt can also be made in satd. alc. soln.; all are sol. in H_2O , MeOH , EtOH , AcOH and, to a slighter extent, acetone; the aq. solns. of the *m*- and *p*-salts slowly become acid; all lose NH_3 slowly in the air; the *m*-salt is slightly hygroscopic. Of the bromobenzoates, the *o*- can be prepd. in C_6H_6 and the *m*-salt in $\text{Et}_2\text{O-EtOH}$; all are sol. in H_2O , MeOH , EtOH , AcOH , slightly in acetone, non-deliquescent. Of the aminobenzoates the *m*-salt can be prepd. by pouring the satd. alc. soln. into an excess of Et_2O . So far, the 3,5-(NH_2)₂ salt has not been isolated. CHAS. A. ROUILLER.

Rate of conversion of cinchonine and of cinchonidine into cinchotoxine (BIDDLE) 2.

FRANK P. UNDERHILL.

The existence of a reducing endo-enzyme in animal tissues. D. F. HARRIS. Dalhousie Univ., Halifax, N. S. *Trans. Nova Scotian Inst. Sci.* 13, 259-78(1913-14).—It is pointed out that a reducing endo-enzyme, reductase, exists in animal tissues. This enzyme is a typical deoxidizer in that it removes O from OsO_4 and from such substances as oxyhemoglobin, which is fully reduced, and methemoglobin, which is reduced to the oxy-condition. Substances containing O, but not in a form wholly removable, can be reduced from the higher to the lower state, as when NaNO_3 is reduced to NaNO_2 , or when Na indigodisulfonate and Na alizarinsulfonate are, respectively, reduced to their pale chromogens. It is further shown that reductase can also reduce metallic salts containing no O from their higher to their lower forms, as when FeCl_3 is reduced to FeCl_2 . Further, certain pigments containing no O, such as sol. Prussian blue and methylene blue, are reduced to the pale or white chromogenic conditions. In conclusion the tissue respiratory ferments are discussed. Cf. C. A. 9, 89.

H. JERMAIN CREIGHTON.

Peroxidase in beer yeast. A. BACH. *Arch. sci. phys. nat.* 39, 497-507(1915).—The facts observed by Harden and Zilva (C. A. 8, 3060), that in a mixt. of *p*-phenylenediamine and H_2O_2 yeast produces a violet color, cannot be attributed to the action of peroxidase for in a series of expts. with yeast suspensions, previously boiled, similar colorations were produced, results incompatible with the hypothesis of the intervention of an enzyme; further, not in a single instance did the yeasts examd. give a positive reaction for peroxidase with the usual reagents (guaiacol, pyrogallol, hydroquinone). The formation of violet dyes in the oxidation of *p*-phenylenediamine by H_2O_2 occurs only in the presence of acids and the quantity of dye increases directly with the acidity to a limit which corresponds nearly exactly to the ratio *p*-phenylenediamine:acid = 1 mol.:0.5 mol. Beyond this limit no more violet color is produced, but brown and yellow-brown shades instead. The reaction observed by Harden and Zilva is solely due to the acidity of yeast and not to the intervention of peroxidase. In a mixt. of *p*-phenylenediamine and H_2O_2 finely divided silk accelerates the formation of the violet dye in the same manner as yeast. Yeast exts. purified by ultrafiltration contain considerable quantities of invertase and maltase, but no peroxidase. Neither top nor bottom yeasts, both cultivated in pure state, gave any peroxidase reactions. The same results were obtained when yeasts were cultivated in a current of air.

L. W. HAAS.

Enzymes: the synthetic and hydrolytic oxynitrilase. II. VERNON K. KRIEBLE. *J. Am. Chem. Soc.* 37, 2205-13(1915); cf. *C. A.* 7, 3976; Rosenthaler, *C. A.* 7, 3762; Bayliss, *C. A.* 7, 3764.—The benzaldehyde used was prepd. by treating the lab. stock with NaHCO_3 , extg. with Et_2O , drying with Na_2SO_4 and distg. *in vacuo* directly into a buret, flooding the app. with N and connecting the buret with a large reservoir of N. When not in use, the tip of the buret was kept under H_2O . The mandelonitrile (a), from benzaldehyde, shaken with aq. HCN in a bottle flooded with N until the calcd. amt. of HCN was absorbed, was never obtained quite pure; when hydrolyzed it gave only about 82% of the calcd. amt. of NH_4Cl and in 168 vols. of H_2O yielded only 13.7% free HCN at equil. instead of the calcd. 19%. The rate of reaction and the equil. point between HCN and benzaldehyde in the presence of oxynitrilase were studied to det. whether there was any difference in the enzyme obtained from various sources and in enzyme from the same source but obtained by various methods and subjected to certain treatments. The benzaldehyde and enzyme soln. were stirred 0.5 hr. at 25° in a N atm., the HCN added and the rate of reaction followed by withdrawing measured vols. of the mixt. from time to time, adding to AgNO_3 and HNO_3 , filtering and titrating the filtrate with NH_4CNS . Equil. was very nearly reached 30 min. after adding the HCN. Expts. with exts. of wild cherry leaves, the acetone ppt. of the latter, and of peach leaf ext. and Kahlbaum sweet almond and peach kernel emulsins all gave practically the same equil. point. The same was true when the extns. were continued for different lengths of time and with different amts. of H_2O . A repetition of some of the methods given by R. for the sepn. of the hydrolytic from the synthetic enzyme has thus far given no evidence of the possibility of such a sepn. C. A. R.

The individuality and polyvalency of trypsin. FRANCESCO MARRAS. Univ. Sassari. *Centr. Bakt. Parasitenk. I Abt.* 75, 193-7(1915).—Although heating destroys the ability of trypsin to digest all substances but gelatin, an antiserum made by injecting it into a dog does not differ from that made from active trypsin as detd. by the complement fixation and precipitin tests. These facts indicate that trypsin is only a single enzyme but is polyvalent. Cf. *C. A.* 8, 743.

STANLEY R. BENEDICT.

Method for imbedding small objects. P. A. WEST. *Science* 41, 898-9(1915).—By this simple method is secured a flat surface from which to make sections. The danger of losing the objects while transferring them from the various reagents with a pipet is removed.

H. DUBIN.

New test of blood-serum and cerebrospinal fluid in syphilitic involvement of the nervous system. ALFRED GORDON. *N. Y. Med. J.* 101, 343-5(1915).—To 0.5 cc. blood-serum in a t. t., slowly add, in the center of tube, 5 drops of 1:100 soln. of HgCl_2 . In normal serum an immediate cloudiness appears, rapidly increasing in density and, at the end of 10 min., presents a thick, gray mass with a slightly greenish tint. In syphilitic serum a foamy upper layer forms above a transparent serum. On standing overnight the former coagulum falls to the bottom; the latter dissolves. Of 29 cases all but 2 ran parallel to Wassermann tests. In cerebrospinal fluid the same procedure gives cloudiness in syphilitic serum but in normal it remains clear. Out of 9 cases all but one ran parallel to the Wassermann test. The intensity of cloudiness varies with the intensity of the Wassermann.

M. RINGER.

A disturbing factor in Barfoed's test. WILLIAM H. WELKER. *J. Am. Chem. Soc.* 37, 2227-30(1915); cf. *P. Am. Soc. Biol. Chem.* 1909, 180; Mathewson, *Diss.*

Columbia Univ. 1912.—A series of expts. with solns. containing varying amts. of glucose and NaCl showed that very small amts. of the latter interfere with Barfoed's test. In the absence of NaCl, 1 cc. of reagent and 9 cc. glucose soln. heated 2 min. in boiling H_2O give a very definite reduction when the concn. of the glucose is 0.08%; 0.04% glucose gives a faint reduction. At room temp., a NaCl concn. of 0.16% does not but one of 0.32% does give a ppt. with the B. reagent; glucose seems to favor the formation of opalescent (colloidal) solns. when added to the reagent and NaCl. The greenish white ppt. formed by NaCl contains Cu, Na, Cl and the AcOH radical; when formed at room temp. it tends to form colloidal solns.; boiling hastens the pptn. C. A. R.

Recent methods of bacterial air analysis. G. L. A. RUEHLE. *Am. J. Pub. Health* 5, 603-7(1915).—The author compares the 3 methods of air analysis for germ content: water-filtration method of Rettger, sand-filtration of Am. Public Health Assoc., and a modification of the latter devised by the author, which consists in eliminating the lower rubber stopper and bolting cloth supports and fusing the small tube into the larger one, thereby causing the layer of sand to rest upon a layer of cotton which in turn rests on the shoulder made by the junction of the large and small tubes. The upper rubber stopper is replaced by one of cork. On comparison it was found that the sand filter gave 92% efficiency, while the Rettger tubes gave 93%, and the modified method gave 96%. The advantages and disadvantages of each method are pointed out. J. G.

C. BACTERIOLOGY.

ERNEST D. CLARK.

The Schumann rays as an agent for the sterilization of liquids. W. T. BOVIE. *Botan. Gaz.* 60, 144-8(1915).—By the use of a sterilizer such as is described by Billion-Daguerre (*C. A.* 4, 470, 2022) B. shows that the bacteria would not be exposed to sufficient light to kill them. An improved sterilizer reduced the bacterial count of the water from 50 to 4 per cc., and the fungal count from 3 to 1 per cc. In none of the experiments was the water completely sterilized. B. H.

Some filamentous fungi tested for cellulose-destroying power. F. M. SEAKS. *Botan. Gaz.* 60, 149-53(1915).—S. used 30 species of *Penicillium* and 10 species of *Aspergillus*. The cellulose-destroying power of these organisms was detd. with two different sources of N: $(NH_4)_2SO_4$ -cellulose-agar and a peptone-cellulose-agar. The $(NH_4)_2SO_4$ medium was prepared as described by McBeth and Scales (*C. A.* 7, 1527) and the peptone medium by substituting 1 g. per liter of peptone for the $(NH_4)_2SO_4$. In almost all cases the fungi possess the power of destroying cellulose. B. H.

Alcohol and iodine as germicides. ALBERT COMSTOCK. *N. Y. Med. J.* 101, 305-6(1915).—Germicidal action was tried on *B. subtilis*, *B. anthracis*, *B. coli communis*, *Staphylococcus pyogenes aureus*. The germicides were: 95% and 70% alc., tincture of I, and both together. I as generally employed was found to be a thoroughly germicidal substance, whereas alc. had but little antiseptic value. M. RINGER.

Utilization by the animal organism of sugar produced from sucrose and nutritive mineral salts. WILHELM VÖLTZ. *Z. Spiritusind.* 38, 235-6(1915).—Comparative expts. (on a dog) with dried brewers' yeasts and with yeast propagated in a sugar soln. contg. mineral matter as the only other constituent, led V. to the conclusion that there are no differences between these yeasts as to digestibility and utilization of the nutritive constituents. The function of the liver in urea formation from amino acids. B. C. P. JANSEN. Univ. Amsterdam. *J. Biol. Chem.* 21, 557-61(1915).—The surviving liver of dogs and cats was perfused with blood and blood diluted with Ringer soln. to which, after perfusion for $\frac{1}{2}$ hr., were added varying amts. of $(\text{NH}_4)_2\text{CO}_3$, glycocoll, leucine, alanine and ereptone. The amt. of urea in the perfusing liquid was detd. after 30 min. and after an hour of perfusion by the urease method, after removing the protein by the addition of an equal vol. of 2% HCl and an equal vol. of 6% HgCl_2 soln. The perfusion app. of Mandel-Embsden was used; in it good arterialization of the blood is effected. Increase in the amt. of urea was observed in all the 26 expts. and, contrary to the results obtained by Fisk and Karsner (*C. A.* 8, 729), it is evident that the liver can play an important part in the formation of urea from amino acids. A. P. L.

The metabolism of creatine and creatinine. X. The relationship between creatine and creatinine in autolyzing tissue. VICTOR C. MYERS AND MORRIS S. FINE. N. Y. Post-Graduate Med. School. *J. Biol. Chem.* 21, 583-99(1915).—In pure soln. creatine is transformed into creatinine and creatinine into creatine at a const. rate of about 0.5% at body temp. After 11 months an equil. is established between the 2 substances. In muscle tissue autolyzing at body temp. the transformation of creatine to creatinine is 3 times as fast as in pure soln., the change being sufficiently rapid to be almost directly comparable with the rate of creatinine formation in the body. Comparatively small changes in temp. influence the rate of transformation in much the same way that fever increases the creatinine elimination. There was no destruction of creatine or creatinine in the autolyzing mixts. Comparable results were obtained with rabbit, cat and hen muscle but with dog muscle the creatinine did not increase after a certain period and there was a loss in total creatinine. Expts. with autolyzing human blood and rabbit liver showed an increase in both the creatine and the creatinine. "Since the creatine of the muscle tissue has a relatively definite concn. for a given species of animals, it is logical to assume that it is very const. for an individual animal. In the autolysis expts. with muscle tissue it has been shown that creatine is converted into creatinine at a very const. rate. This same reaction in the body would account for the well-known constancy in the excretion of creatinine. Since the muscle creatine and urinary creatinine are const., there must be a definite ratio between the two. This would be equiv. to a daily conversion of creatine to creatinine of about 2%. When creatine is administered to man or animals, there is a slight conversion to creatinine which corresponds very well with this figure; and in autolyzing muscle tissue there is practically

the same rate of transformation." The data constitute a strong set of arguments supporting the authors' hypothesis even though they "cannot be regarded as directly bearing upon the relationship existing *in vivo* between creatine and creatinine."

A. P. LOTHROP.

The influence of the composition and amount of the mineral content of the ration on growth and reproduction. E. V. MCCOLLUM AND MARGUERITE DAVIS. Univ. Wisc. *J. Biol. Chem.* 21, 615-43 (1915).—Expts. were performed using diets consisting of milk powder, casein, butter fat, agar, dextrin and sucrose and varying amts. of a salt mixt. The rations ranged from an acidity of 14.3 cc. to an alkalinity of 102.1 cc. of *N* soln. per 100 g. "Provided the other factors in the ration are adequate, young rats can grow normally and remain in apparent good health on rations whose base content varies widely in amt. Four of the rations were highly acid yet growth and well-being were not markedly interfered with. Growth to the normal adult size at the usual rate and continued well nourished appearance is not sufficient evidence that a ration is fully adequate. Only when normal reproduction and rearing of young is repeated at normal intervals can a ration be said to be physiologically sufficient." On the diets employed there was in all cases a failure to repeat reproduction at normal intervals. When part of the dextrin and casein was replaced by wheat and the mineral content of wheat was corrected by the proper salt addition, reproduction was repeated normally and it was evident that some other factor than the mineral content was responsible for the inadequacy of the rations. The most satisfactory ration consisted of wheat, casein, dextrin, butter fat and salt mixt., the alkalinity of the ration being 17.9 cc. of *N* soln. per 100 g.

A. P. LOTHROP.

Creatinuria. ALONZO E. TAYLOR. Univ. Penn. *J. Biol. Chem.* 21, 663-5 (1915).—In the child creatinuria is not dependent upon a low carbohydrate intake and there is evidently a partition of creatine-creatinine in the urine of children. Ketones, in the amts. in which they are present in children's urine, have no effect on the reading in the Folin method for creatinine. In expts. with 2 children on a generous carbohydrate intake, 19 and 40% of the creatine-creatinine elimination was in the form of creatine. "The absolute figures for creatine-creatinine compare approx. with those noted in adults, when the wts. of the children and the probable masses of muscular tissue are considered, thus confirming the Folin-Shaffer postulate of the relation of creatinine to mass of muscle tissue."

A. P. LOTHROP.

Animal sugar. D. VITALI. *Giorn. farm. chim.* 64, 97-101 (1915).—V. discusses the presence of glycogen in the animal organism in connection with carbohydrate metabolism and emphasizes the value of carbohydrates in the diet. H. S. PAINE.

Importance of extractives in the diet. H. ARON. *Monatsschrift Kinderheilkunde* 13, No. 8 (1915); *J. Am. Med. Assoc.* 65, 205.—Expts. with rats showed that when fed abundantly with casein, fat, starch, salts and an ext. of wheat bran, the animals thrived and constantly increased in wt., while on the same diet without the wheat bran ext. they lost wt. and finally died. Ext. of malt gave results similar to ext. of bran but its action was slower. A. tried to keep the technic of his expts. like that of Osborne and Mendel for purposes of comparison.

L. W. RIGGS.

Nutrition and metabolism of an infant on artificial food. E. HELLENSEN. *Nord. Med. Arch.* 48, Nos. 3-4, 120 pp. (1915); *J. Am. Med. Assoc.* 65, 566.—This research is accompanied by 31 tables showing the metabolic findings and the conditions with regard to nourishment. The data confirm the view that carbohydrates spare the N and C reserves better than fat. Carbohydrate food has a marked influence on the mineral metabolism especially of Na. Carbohydrates and fats cannot substitute each other indiscriminately as each has its specific action on the whole metabolism of force and matter, which is a factor of great importance for their role as food. L. W. R.

Some studies on sugar in infant feeding. L. PORTER, San Francisco AND C. H. DUNN, Boston. *Am. J. Dis. Children* 10, No. 2(1915); *J. Am. Med. Assoc.* 65, 466. —From observations with 18 infants the authors think that the idea of sugar injury or sugar intoxication has been overemphasized, particularly in cases of mild fat intolerance.

L. W. RIGGS.

ABNORMAL.

Studies on tissues of fasting animals. S. MORGULIS, P. E. HOWE AND P. B. HAWK. *Biol. Bull.* 28, 397-407(1915).—Largely histochemical. B. HOROWITZ.

Is pathologic metabolism in the parental organism responsible for defective and monstrous development of the offspring? E. I. WERBER. Woods Hole and Princeton Univ. *Bull. Johns Hopkins Hosp.* 26, 226-9(1915).—When fertilized eggs of *Fundulus heteroclitus* are subjected to the action of solns. of acetone and butyric acid, there are produced an unusually large number and variety of monsters, which resemble morphologically those which have been described in human beings. The opinion is expressed that toxic substances produced by disturbances of metabolism may cause the development of monsters through the poisoning of the embryo or germ-cell. Success in the production and control of monstrous or defective development experimentally in mammals may eventually lead to means by which their occurrence can be checked. The problem is one of great medical significance. A. P. LOTHROP.

Relation of gas bacillus to infectious diarrhea and other digestive disturbances of childhood. P. H. SYLVESTER AND F. H. HIBBEN. Boston. *Arch. Pediatrics* 32, No. 6(1915); *J. Am. Med. Assoc.* 65, 555.—The following routine gave excellent results: Give unpasteurized lactic acid milk exclusively until the stools are free of bacilli for 3 successive plants at 2- or 3-day intervals. When free from the gas bacillus, continue a small amt. of the lactic acid milk daily, and gradually increase the amt. of food to normal caloric requirements, by adding skimmed milk and with caution small amts. of carbohydrates in the form of maltose or well cooked starches, testing for gas from time to time. Add fat in very small amts. to the diet after weeks or months, watching stools frequently for undigested fat. When there is a recurrence of the gas bacillus the treatment should be repeated. L. W. RIGGS.

Functioning of the pancreas and its relation to the pathogenesis of diabetes. A. VISENTINI. *Intern. Monatssch. Anat. Physiol.* 31, Nos. 10-2(1915); *J. Am. Med. Assoc.* 65, 655.—The conclusions of this paper confirm anew and apparently with certainty that the islands of Langerhans, and these alone among the elements of the pancreas, control the metabolism of carbohydrates in the animal organism. This paper, which fills over 100 pages, was awarded the Warren triennial prize at Boston in 1913. L. W. RIGGS.

Metabolism study of a case of chronic urticaria. JACOB ROSENBLUM AND M. C. CAMERON. Pittsburgh, Pa. *J. Cutaneous Dis.* 33, 15-7(1915).—The female patient afflicted with chronic urticaria for many years was kept on an exact diet. There was a retention of 5.08 g. N in 3 days. The urea N was low and the fecal N was 3 times the normal. During the first 2 days the amount of neutral S was large, but on the 3rd day the ethereal sulfates increased. The fat in the stools was above normal, whereas the quantities of Ca and Mg excreted in the urine and feces were normal.

M. RINGER.

Homogenized olive oil and fat-free milk mixtures in case of difficult feeding. M. LADD. Boston. *Arch. Pediatrics* 32, No. 6(1915); *J. Am. Med. Assoc.* 65, 554. —L. describes a method of administering homogenized olive oil as a substitute for cow fat in the cases of fat intolerance. L. W. RIGGS.

Starch digestion in children, with some clinical observations. H. H. YERINGTON

AND C. T. WETMORE. Stanford Univ. *J. Am. Med. Assoc.* 65, 569-72(1915).—A study of 372 stool analyses from 338 children ranging from 1 to 14 years of age showed that there is a type of indigestion in children brought on by continued use of a diet composed principally of carbohydrates. This condition can be relieved by a partial elimination of the starches, and giving a mixed diet fed at proper intervals, for which parents must be supplied with an accurate written dietary. Frequent exam. of stools is absolutely necessary to check up the progress of the case. Before attempting to correct the dietary, the oral cavity should be examd. as decayed teeth, inflamed tonsils, and nasal secretions play a most important part in the proper digestion of the child's food.

F. PHYSIOLOGY.

ANDREW HUNTER.

Experimental and chemical studies of the blood. I. J. J. ABEL. *Science* 42, 135-47(1915).—A. reviews briefly the history of blood-letting and describes a new procedure to which he gives the name, *plasmapheresis*. According to this method, blood is withdrawn from an animal and clotting prevented by the addition of leech ext. An equal vol. of Locke's fluid is added and the mixt. centrifuged until the corpuscles have settled out. The supernatant plasma is drawn off, replaced by Locke's fluid, the corpuscles are stirred up and the new mixt. returned to the animal. By this means, as much as twice the vol. of blood in the body has been removed from a dog by repeated bleedings in a single day, with no apparent injury. A study was made of the chem. changes in the blood during plasmapheresis; blood-pressure was observed, and blood-counts taken. A. describes also a process called "vividiffusion" for the isolation of various constituents of the blood of a living animal, suggesting it as a means of studying the organs of internal secretion. II. *Ibid* 165-78.—A general discussion of internal secretions, with special reference to epinephrine.

H. DUBIN.

Influence of pregnancy on the hyperglucemia of pancreatic diabetes. A. J. CARLSON AND H. GINSBURG. *Am. J. Physiol.* 36, 217-22(1915).—Pancreatectomy in bitches near full term is not followed by hyperglucemia and glucosuria as long as the fetuses are alive and the placental connection not severed.

J. F. LYMAN.

The alleged influence of epinephrine and of the sympathetic nervous system on the tonus of skeletal muscle. YAS KUNO. *J. Physiol.* 49, 139-46(1915).—Epinephrine, which has a marked influence on the nerve endings of the sympathetic system, has no effect on tonus of skeletal muscles in frogs. Division of the rami communicantes does not affect the tonus of the hind legs. Hence the sympathetic fibers have no significance for muscle tonus. Tonus is markedly affected after division of the anterior roots of the spinal nerves.

J. F. LYMAN.

Jaundice of the newly born. F. BANG. *Hospitalstidende* 58, No. 26(1915); *J. Am. Med. Assoc.* 65, 566.—B. found that the blood in the umbilical cord of 24 newborn infants contained bile pigment, which increased in amt. during the first few days but began to subside after 3-5 days, though giving a positive reaction on the 10th day. Icterus in the newly born appears to be a physiologic condition. The Gmelin-Sunde technic was employed in testing for bile pigments.

L. W. RIGGS.

Proteolytic ferments in portal blood. F. H. FALLS. Chicago. *J. Am. Med. Assoc.* 65, 524-6(1915).—From expts. with dogs F. finds that the portal and the peripheral blood contain a demonstrable increased amt. of proteolytic enzyme at the height of digestion. This is also true of the portal blood in the dog in the fasting state. Under both the foregoing conditions, the portal blood is relatively richer in enzyme than the peripheral blood. The probable source of this enzyme is the intestinal contents at the height of digestion.

L. W. RIGGS.

Protection of parasites in digestive tract against action of digestive enzymes. W. E. AND E. L. BURGE. Chicago. *J. Parasitology* June, 1915; *J. Am. Med. Assoc.* 65, 558.—Expts. showed that tapeworms and roundworms from the intestine of the dog are not digested when introduced into activated pancreatic juice so long as they remain alive, but are digested when dead. If any part of them be killed this part is digested. A dead roundworm which is ordinarily digested when placed in activated pancreatic juice, can be prevented from being digested by keeping the dead body wall constantly permeated with nascent O. The oxidative processes of the living parasites enable them to withstand the action of the digestive juices by oxidizing the enzyme soln. immediately in contact with them.

L. W. RIGGS.

Iodine test for functional capacity of the kidneys. M. N. EROFIEV AND V. A. DEGTYAREV. Russ. *Vrach* 14, Nos. 3 and 4(1915); *J. Am. Med. Assoc.* 65, 658.—In 8 healthy persons the duration of elimination of I in the urine ranged from 20.5 to 49 hrs.; in the saliva from 23 to 30 hrs. The opposite was observed in 27 cases of acute and chronic nephritis in which the urine elimination of I was observed from 23 up to 119 hrs., while in the saliva the findings were positive from 28 to 189 hrs. With healthy persons I appears in the urine in from 20 to 53 min. after taking 0.5 g. of KI; in the saliva in from 3 to 26 min. With nephritics I appears in the urine in from 15 to 160 min. and from 4 to 29 min. in the saliva. It is evident that the duration of I elimination by the kidneys does not indicate the condition of renal epithelium, since other organs participate in the same function, and the I may be found for a longer period in the saliva than in the urine.

L. W. RIGGS.

Reaction of the pancreas. J. H. LONG AND F. FENGER. *J. Am. Chem. Soc.* 37, 2213-9(1915).—The fresh pancreas of the steer, hog or sheep is distinctly acid to fresh litmus, no matter how quickly the test is made (even before the organ is removed), and the acid reaction persists after the organ is chilled. It was found that the best method of sepg. the liquid from the minced glands consisted in centrifuging 45 min. at 3000 r. p. m. whereby a sepn. was effected into 3 layers: solid (about 50% of the whole), a more or less reddish liquid, often quite clear (often 25% of the whole), and a top layer containing much fatty matter and part of the protein tissue. After chilling in ice H₂O the liquid layer can be sepd. very completely and on filtration is obtained in bright clear condition. Its H-ion concn. was detd. by the potential method (Hasselbalch cells and a calomel electrode at 20°). The measurements were made within 1-2 hrs. after death, although the potential remained const. through many hrs. Beef and hog pancreas juices secured on various days in June and July all showed approx. a H-ion concn. of 29×10^{-7} ; with sheep pancreas juices, the results are not so regular; 2 juices secured 1 day gave 25.0 and 23.8×10^{-7} and were perfectly clear; 2 others from young lambs gave 10.5×10^{-7} ; another 12.2×10^{-7} ; but in 1 case where there was very little fat and in some other points the behavior was anomalous, the H-ion concn. was 26.6×10^{-8} . The acid reaction of the pancreas is undoubtedly the normal one, and as the juice is rich in phosphates the reaction is probably due to an acid phosphate.

CHAS. A. ROULLER.

G. PATHOLOGY.

H. GIDEON WELLS.

Fat-phanerosis in nerve cells. GIOSUÈ BIONDI. *Arch. path. anat. (Virchows)* 220, 222-33(1915).—In nerve cells of the spinal cord of the dog, autolyzed in NaCl soln., the amt. of contained fat is greater than in nerve cells which undergo fatty changes *in vivo*. The form and distribution of the fat is different; with autolysis, the lipoids which make their appearance are in diffuse form and abundant and the lipid granules lie distributed in the cytoplasm, while with the pathological formation of fat, the lipid materials appear chiefly in the form of granules lying together in groups. This differ-

ence is easily explained since the first process is concerned with dead cell elements, the second with living and active cells. The absence of fat-pigment formation in autolysis may be explained as due to the rate at which the changes take place. The "masked" protoplasm-lipoids in the nerve cells of rabbits seem to be much more firmly bound to the protein than in the dog. The autolytic enzymes seem to be unable to break down this combination.

GEO. T. CALDWELL.

The preservation of the reagents used in the Wassermann reaction. P. G. WESTON. State Hosp., Pa. *J. Med. Res.* 32, 391-8(1915).—Human and rabbit corpuscles were washed and dried *in vacuo* over H_2SO_4 and preserved in amber-colored, glass-stoppered bottles for 15 months, at the end of which time they still retained antigenic properties. Anti-sheep amboceptor was preserved dried on paper for 5 yrs. without deterioration. Some of the paper exposed in a room where there was slight humidity soon lost its amboceptor properties. Complement was preserved at -15° for 3 mos. without deterioration. Human serum, which in a fresh state gave a strongly positive Wassermann reaction, was preserved in a dry state for 19 months without loss of complement-binding properties. Normal and Wassermann plus cerebrospinal fluids were kept in sterilized test-tubes at ice-box temp. for 9 months, at the end of which time the normal fluid gave a negative Wassermann reaction and the plus fluid a positive reaction. Neither fluid had been heated at any time. No anticomplementary bodies developed in the normal fluid.

GEO. T. CALDWELL.

The pyrogenic action of *Bacillus typhosus*. D. H. BERGEY. Univ. Pa. *J. Med. Res.* 32, 433-44(1915).—A large part of the pyrogenic action of *B. typhosus* is due to an intracellular poison, and only a slight effect, if any, is due to a sol. toxin. The serum of animals immunized against culture filtrates of *B. typhosus* and against dead bacilli exerts a slight antipyretic action. There is not sufficient evidence, in the results obtained by the protective use of the serum of immunized animals, to suggest that similar serums would have much influence as therapeutic agents.

G. T. C.

A study of the effect of anaphylaxis and leech extract on the coagulation of the blood. R. I. LEE AND BETH VINCENT. Boston. *J. Med. Res.* 32, 445-54(1915).—Probably many substances and many conditions act in inhibiting or preventing coagulation of the blood; these vary from extreme cold, oxalate and similar salts which ppt. the Ca, to anaphylaxis and leech ext. The authors believe that "anti-thrombin" instead of being really one substance is the effect of many substances or conditions upon some of the essential principles of coagulation. The alteration of coagulation in anaphylaxis and leech ext. blood is attributed to a definite effect on the blood platelets and not to the introduction of antithrombin.

GEO. T. CALDWELL.

Cell enzymes and energetics in relation to cancer. L. D. BRISTOL. Univ. N. Dakota. *J. Med. Res.* 32, 475-86(1915).—The conclusion reached by the author is that cancer is the result of localized, unchecked over-combustion or hyperoxidation, in epithelial cells.

GEO. T. CALDWELL.

The persistence of typhoid antibodies in the blood of inoculated persons as estimated by agglutination tests. G. DREYER AND A. C. INMAN. London. *Lancet* 1915, II, 225-6.—At least 8 months after a single or double dose of typhoid vaccine, the serum of every inoculated person contains relatively large quantities of agglutinins. Persons who received 2 doses of vaccine, usually, but not always, exhibited a higher agglutinin titer than those who had only 1 dose. In persons who had been inoculated before (within 6 yrs.) the agglutinin titer maintained a high level for a longer period than in the case of those not previously inoculated. The importance of repeated inoculations is not so much that it induces of necessity a higher initial immunity but that it insures with certainty a more persistent one.

GEO. T. CALDWELL.

The significance of acetone bodies in the urine. B. DERHAM. Bolton-le Moors. *Lancet* 1915, II, 227-30.—If there is no sugar present in the urine and the acetoacetic acid is transitory, especially if the patient is young and symptoms of gastric catarrh are present, it may be that the site of manufacture of the acetoacetic acid is the intestinal canal, the process being a result of an irregular fermentation of sugar.

GEO. T. CALDWELL.

Experimental treatment of human beriberi with constituents of rice polishings. R. R. WILLIAMS AND N. M. SALEEBY. *Philippine J. Sci.* 10B, 99-118(1915).—W. and S. conclude that treatment with ext. of rice polishings is of distinct value. They show further that allantoin has a beneficial effect in some cases of beriberi, while the vitamine of rice polishings possesses the same property to a greater extent.

H. DUBIN.

Thymus gland in beriberi. R. R. WILLIAMS AND B. C. CROWELL. *Philippine J. Sci.* 10B, 121-5(1915).—There is no apparent connection between beriberi and atrophy of the thymus.

H. DUBIN.

Practical experience with some enriching media recommended for bacteriological diagnosis of Asiatic cholera. OTTO SCHÖHL. *Philippine J. Sci.* 10B, 127-44(1915).—S. suggests that combinations of peptone soln. and selective enriching medium be used, the former because it is more favorable for the rapid growth of the cholera vibrio and the latter because it inhibits the growth of the bacteria other than vibrios more thoroughly than the alkaline peptone soln.

H. DUBIN.

Experiments on the immunization of guinea pigs by the inoculation of avirulent tubercle bacilli in agar. M. A. BARBER. *Philippine J. Sci.* 10B, 145-6(1915).—Some of the animals were given avirulent human bacilli mixed with agar, some were given avian bacilli, and some received an emulsion of the avian strain without agar, as the immunizing dose. The time elapsing between the immunizing and the test doses varied, and in some cases two immunizing doses were given, quite a long interval elapsing between the two doses. In general, the average number of days of survival of the controls is higher than that of any series of treated animals. Two animals outlived the controls by 300 and 330 days, resp.

H. DUBIN.

Typhoid immunity. ALSTAEDT. Lubeck. *Berl. klin. Wochschr.* 52, 681-3(1915).—A series of people who either had typhoid or had received vaccine treatment were tested for intracutaneous reactions with dead typhoid bacilli. The results are used to show that immunity in typhoid is cellular as well as humoral.

J. H. L.

Complement-producing substance in cow milk. R. T. HEWLETT AND CECIL REVIS. Univ. London. *J. Hyg.* 15, 1-10(1915).—Heating to 55° for 30 min. destroys the complementary activity of milk. The complementary substance does not pass through porcelain filters. Removal of the Ca salts from milk with Na oxalate does not decrease its complementary activity. Vigorous shaking at room temp. with or without glass beads has little effect. Cow milk contains a stimulating substance for ox complement, since shaking ox complement with inactivated cow milk increases its activity. This stimulating substance is destroyed by boiling, and the greater part of it can be filtered off with the casein. Stimulation occurs only in the case of cow milk and ox complement. Cow milk inhibited the action of guinea-pig complement. Asses' complement was not stimulated by asses' milk, or human complement by human milk. These results seem to admit of little explanation.

JOHN T. MYERS.

The sterilization of vaccines and the influence of various methods employed on their antigenic properties. FRANK E. TAYLOR. Univ. London. *J. Hyg.* 15, 163-7(1915).—*Staph. pyogenes aureus* vaccine was used. The toxicity was judged by the negative phase of the opsonic index curve and the antigenic power by the height

and length of the positive phase. The toxicity was not increased or the antigenic power decreased by the action of heat, even boiling. The substitution of antiseptics for heat does not definitely decrease the toxicity or increase the immunizing power; the opsonic index does not reach as high a point and in the case of NaF the positive phase is shorter. Ultraviolet rays are uncertain in sterilizing power and do not decrease the toxicity or increase the immunizing power of vaccines. J. T. M.

Influence of autolytic products on tumor growth. G. L. RHODENBURG AND F. D. BULLOCK. *Columbia Univ. Med. Record* 88, 233-4(1915).—The expts. were restricted to chemical products. Of 33 different products of autolysis studied, only nucleinic acid (from animal cells) and phenylalanine showed any retarding influence on transplanted tumors in mice. On retesting these compds. on a larger series of inoculated mice the apparent retarding influence disappeared. A. H. RAHE.

Creatine as index of pregnancy intoxication. C. J. C. VAN HOOGENHUIJZE. *Nederlandsch Tijdschrift Geneeskunde* May 22, 1915; *J. Am. Med. Assoc.* 65, 208.—The findings in 15 cases show that in a normal pregnancy the creatine in the urine is always below 20% of the total creatinine. A creatine figure above 20% indicates the action of toxic influences and may warn of impending eclampsia or other serious difficulty. During the first month of pregnancy the proportion of creatine was 5.8%, the third month 18.9%, and the eighth month 15.1%. It is suggested that the finding of creatine in the urine might reinforce the diagnosis of pregnancy in doubtful cases, after the exclusion of other sources of creatine in the urine. L. W. RIGGS.

Intestinal obstruction. A proteose intoxication. G. H. WHIPPLE. *Univ. Cal. J. Am. Med. Assoc.* 65, 476-8(1915).—The poison under discussion may be obtained from the fluid above an intestinal obstruction, from a closed washed loop of small intestine, or from the mucosa of a closed loop or a loop draining externally through an enterostomy wound. The mucous membrane forms the poison and passes it into the blood stream. By destruction of the mucosa by NaF the formation of the poison ceases. Five vols. of 95% alc. completely ppt. this poison, whether the fluid is freshly removed from an intestinal loop rich in albumins, or has been digested to a clear broth. This ppt. is insol. in Et₂O but freely sol. in H₂O. The poison may be further purified by pptn. with an equal vol. of satd. (NH₄)₂SO₄, the ppt. collected in a centrifuge, dried and again dissolved in H₂O and boiled with a drop of AcOH to remove the last trace of albumin. Dialysis of this aqueous soln. against normal salt will remove most of the (NH₄)₂SO₄ but will not change the toxic action of the poison which does not dialyze. The purified soln. of the poison gives the biuret, ppts. with phosphotungstic acid or satn. with NaCl. Estimations from the dry wt. show that 0.1 g. given intravenously is fatal to a 15-pound dog. The process of chem. isolation gives a primary proteose and eliminates all other substances except NaCl and (NH₄)₂SO₄. The injection of this toxic proteose causes a marked rise in the incoagulable N of the blood from a normal of 30 mg. to 70 or 80 mg. shortly before death, the change taking place within 3 hrs. Dogs with intestinal obstruction may show incoagulable N as high as 200 mg. L. W. RIGGS.

Botulism, an experimental study. Preliminary report. E. C. DICKSON. *San Francisco. J. Am. Med. Assoc.* 65, 492-6(1915).—D. presents the following conclusions: The presence of animal protein is not essential, as hitherto supposed, for the development of the toxin of botulism. The toxin may be produced in a medium made from string beans or from peas. An acid reaction of as much as 3.2% to phenolph. does not prevent the formation of the toxin. The toxin produces some disturbance of the circulatory system which leads to hyperemia and hemorrhages in the meninges, and in the central nervous system, and to thrombosis in the arteries and veins of the meninges and of the central nervous system. The lesions in the nerve cells are not

due to a specific action of the toxin on the cell protoplasm, but they are secondary to disturbances of blood supply.

L. W. RIGGS.

Alkaptonuria. G. SODERBERGH. *Nord. Med. Arch.* 48, Nos. 3-4, 130 pp.(1915); *J. Am. Med. Assoc.* 65, 566.—19 plates, 18 other illustrations and 17 graphic tracings are given. The Wassermann reaction was strongly + in the principal case of alkaptonuric ositis, but became — under a month of Hg inunctions. It became + in 3 of 4 cases immediately after the patients had taken a 5 g. dose of tyrosine, the mother substance of homogentisic acid. Although the Wassermann was + there was nothing else in the signs or antecedents to indicate syphilis. The bone changes resemble those of Paget's disease in which the Wassermann reaction is also frequently + with nothing otherwise to suggest syphilis.

L. W. RIGGS.

Spontaneously precipitated albumin in urine. JACOB ROSENBLUM. *N. Y. Med. J.* 101, 23(1915).—R. cites a case where albumin of urine was spontaneously pptd. The filtrate showed no albumin although the residue contained 1.25 g.

M. R.

Active immunization to hay fever. SEYMOUR OPPENHEIMER AND MARK J. GOTTLIEB. *Biochem. Lab., Coll. of P. and S. and Lab. for Chem. Research.* *N. Y. Med. J.* 101, 229-32(1915); see *C. A.* 9, 1937.

M. RINGER.

Colloidal gold test on spinal fluid; in paresis and other mental diseases. CHAS. J. SWALM AND ABRAHAM L. MANN. Norristown, Pa. *N. Y. Med. J.* 101, 719-23 (1915).—The authors employed Carl Lange's colloidal gold test in 70 cases of paresis. They found 90% gave positive reactions although they doubt the specificity. The technic of the method is given.

M. RINGER.

Recent studies of pancreatic secretion. MAX EINHORN. *N. Y. Pst. Grad. Med. School. Med. Record* 87, 967-72(1915).—This paper contains a tabulation of data pertaining to duodenal contents in many pathologic cases.

M. RINGER.

H. PHARMACOLOGY.

ALFRED N. RICHARDS.

Physiological action and behavior of some derivatives of benzene compared to those of cyclohexane. EDUARDO FILIPPI. Florence. *Arch. farm. sper.* 18, 178-211 (1914).—The pharmacol. effects of toluene, *o*-, *m*-, and *p*-xylene, mesitylene, benzyl alc., cyclohexane, *o*-, *m*-, and *p*-methylcyclohexanol, methyl-, dimethyl- and trimethylcyclohexane, cyclohexanone, methyl-, dimethyl- and trimethylcyclohexanone are compared.

A. W. DOX.

The effect of certain drugs on the respiration and gaseous metabolism in normal human subjects. HAROLD F. HIGGINS AND JAMES H. WEAVER. Boston. *J. Pharmacol.* 7, 1-30(1915).—Therapeutic doses of the following drugs were used: Atropine produced no effect on the respiration or respiratory center, but produced bronchial dilatation with increased metabolism and a fall in pulse rate with a subsequent rise. Caffeine stimulated the respiratory center with increase in the respiratory rate and metabolism; there was no change in pulse rate and either bronchial dilatation or none. Camphor had no effect on the respiratory center, respiratory rate, pulse rate, slightly increased the metabolism and either dilated or had no effect on the bronchi. Strychnine produced no effect on the respiration, bronchi, pulse or metabolism. Morphine depressed or had no effect on the resp. center, constricted the bronchi and slightly increased the resp. rate, but decreased or had no effect on metabolism and the pulse rate. Heroin differed from morphine in that there were no effects on the resp. rate and metabolism. The sensitivity of the resp. center was followed by making frequent detns. of alveolar CO₂, testing by the Haldane method. Gaseous metabolism was obtained by the Tissot method or Benedict universal app.

P. J. HANZLIK.

Observations on the effect of intravenous injections of sodium phosphate. ISIDOR

GREENWALD. Roosevelt Hosp., N. Y. City. *J. Pharmacol.* 7, 57-61(1915).—The results reported by Starkenstein (*C. A.* 8, 3472) that the administration (*per os*, intravenous or subcutaneous) of ortho-, meta- and pyro-phosphates, also citrate, gives rise to convulsions are not confirmed for the intravenous injection of the phosphates by G.

P. J. HANZLIK.

Action of veratrum viride. WILLIAM CRAMER. Edinburgh. *J. Pharmacol.* 7, 63-82(1915).—A 15% ext. of the crude drug and a commercial prepn. were used. In small doses veratrum produces reflex slowing of the respiration, a fall of blood pressure due to vasodilatation, and a slowing of the pulse due to stimulation of the vagus center. The integrity of the vagus nerves is necessary for these effects. After stimulation of the vagus, paralysis occurs so that a 2nd or 3rd dose is ineffective. With large doses the drug in addition to the effects just mentioned paralyzes the cardio-inhibitory nerve endings of the vagus and has also a direct action on the medullary centers leading to vasoconstriction and to paralysis of respiration. The general result of a large dose is complex and irregular. It was not decided whether the action of veratrum viride is due to veratrine or protoveratrine. The drug is therapeutically valuable (recommended dose, 0.5 cc. of Brit. Pharm. tincture).

P. J. HANZLIK.

Action of drugs on the isolated gall-bladder. CHARLES C. LIEB AND JOHN E. MCWHORTER. New York. *J. Pharmacol.* 7, 83-98(1915).—Atropine and epinephrine relaxed, NO_2 and bile salts depressed, strophanthin and BaCl_2 constricted and morphine in therapeutic doses was ineffective on strips of surviving gall-bladder of the dog. Atropine and NO_2 would seem to be indicated in gall-stone colic.

P. J. HANZLIK.

The effects of chelidonin on smooth muscle. PAUL J. HANZLIK. Cleveland. *J. Pharmacol.* 7, 99-119(1915); see *C. A.* 9, 658.

P. J. H.

The comparative action of the stereoisomers of hydroxyhydrindamine. YASUO IKEDA. Cambridge. Eng. *J. Pharmacol.* 7, 121-4(1915).—The hydrochlorides of

the *l*- and *d*-hydroxyhydrindamine $\text{C}_8\text{H}_9\text{CH}_2\text{CH}(\text{CHOH})\text{CH}_2\text{NH}_2$ are white, cryst. salts,

sol. in H_2O , sparingly sol. in alc. and powerfully optically active. Both varieties depress smooth and cardiac muscle, cause vasodilatation, act as mild antiseptics, but are innocuous systemically in intact animals. The *d*-salt is more toxic than the *l*-salt, both being mild, general protoplasmic poisons.

P. J. HANZLIK.

The antitoxic action of rattlesnake serum on rattlesnake venom, with a note on the percentage of total solids of the serum and bile. WM. H. WELKER AND JOHN MARSHALL. Philadelphia. *J. Pharmacol.* 7, 125-8(1915); cf. *C. A.* 9, 1806.—Each of the blood sera of the 2 species of rattlesnakes (*Crotalus atrox* and *C. adamanteus*) has antitoxic action for the venom of other species.

P. J. HANZLIK.

The toxicity of certain hirudin preparations. E. K. MARSHALL, JR. Baltimore. *J. Pharmacol.* 7, 157-68(1915).—Prepns. of the commercial hirudin of Sachse & Co. proved to be very toxic for dogs, less so for rabbits. 20 to 25 mg. per kg. was fatal to dogs with symptoms of severe diarrhea and continuous vomiting. Smaller doses (1.3 mg. per kg.) gave definite symptoms of depression, vomiting and diarrhea. Autopsy showed a marked congestion of intestinal tract with hemorrhagic patches in the lungs and pericardium and occasionally the spleen. The toxic effects were shown to be due not to the hirudin of the prepn., but to some other substance, such as sepsin possibly. Leech ext. obtained by extn. with H_2O and coagulation of protein at 82 to 85° is non-toxic in quantities used to render circulating blood non-coagulable.

P. J. HANZLIK.

Action of calcium salts. CHAS. O. JONES. Liverpool. Biochem. Lab. *Brit.*

Med. J. 1915, I, 462-3.—A study of the excretory powers of animals for Ca salts and the protection of the body against excess. Rabbits were used and CaCl_2 in 10% soln. was administered intravenously. When injected into the blood in small quantities it is excreted by the kidneys as phosphates, carbonates and oxalates. In larger quantities the bowels also take part in excretion and eliminate Ca as inorganic salts. In greater quantities the kidneys are thrown out of action and the intestines alone effect the excretion, until a toleration point is again reached, when the kidneys resume their action. In still greater quantities Ca is excreted by the intestines as Ca-soap. In excessive amount, intravascular clotting and death ensue. The toleration point can be raised by injecting increasing doses of CaCl_2 provided time is given for the animal to complete excretion of one injection before the next is made. M. RINGER.

Composition and pharmacological action of Spiritus aetheris nitrosi. C. R. MARSHALL AND ELIZABETH GILCHRIST. *Brit. Med. J.* 1915, II, 125-8.—Sweet spirits of niter contained not only EtNO_2 and aldehyde but also EtNO and paraldehyde. Nitrite was estd. by the official (Brit. Pharm.) method with KI and dil. H_2SO_4 using a nitrometer charged with Hg instead of with brine. The aldehyde was detd. colorimetrically with Schiff's reagent. Paraldehyde was converted into aldehyde by distn. with dil. acid and estd. by difference. Evidence of the presence of EtNO_2 was obtained in some instances, but the authors were unable to devise a method for its detn. in the presence of EtOH , EtNO_2 and aldehyde. An approximation was obtained by detg. the total N by Dumas' method and estg. the nitrate by difference. It is not probable that any of the activity of sweet spirits of niter can be due to the paraldehyde. The EtOH accounts for the carminative action of the prepn. but does not explain the whole effect, particularly the vasodilating action. Acidity is of no effect, and in consequence the activity of sweet spirits of niter must be due to EtNO_2 , EtNO , or to acetaldehyde, the only other ingredient. Pharmacological expts. showed that the activity of the prepn. was due to EtNO_2 . Diln. with water causes an evolution of nitrite and this loss occurs in some degree even in a filled stoppered bottle in the dark. A. H. R.

Biochemical properties of chrysarobin. J. F. SCHAMBERG, G. W. RAIZISS AND J. A. KOLMER. Philadelphia. *J. Cutaneous Dis.* 33, 98-116(1915).—Chrysarobin has 3 primary properties: (1) resistance to oxidation on exposure to air, (2) strong reducing action, (3) chem. affinity and firm union with the proteins of the skin. The possibility is suggested that the favorable influence of chrysarobin on psoriatic lesions is due to a chem. union and abstraction of O, resulting in a restraining influence upon the proliferative power of epithelial cells. M. RINGER.

Study of the germicidal activity of chrysarobin and certain other medicaments used in psoriasis. JAY F. SCHAMBERG, JOHN A. KOLMER AND G. W. RAIZISS. Phila. Polyclinic and Coll. for Graduates in Med. *J. Cutaneous Dis.* 33, 1-15(1915).—Having failed to secure direct evidence of the parasitism of psoriasis, the authors sought to det. whether the known remedies produce their beneficial results through germicidal effect on the skin or through some biochem. action. Chrysarobin, pyrogallie acid locally and As internally, do not exert their curative effects through germicidal action upon cocci of psoriatic patches, *Staphylococcus epidermis albus* being taken as an example. This is supported by indifferent effects of strong germicidal substances, e. g., phenol, formalin, calomel, on psoriatic lesions. Cf. C. A. 9, 936. M. R.

The elimination of soluble radium salts taken intravenously and per os. HARVEY A. SEIL, CH. H. VIOL AND M. A. GORDON. Pittsburgh. *N. Y. Med. J.* 101, 896-7 (1915).—The authors intravenously injected 0.1 mg. Ra in a man. The main part was eliminated through the feces. It was rapid during the first 3 or 4 days, slower for the next 6 or 7, then very slow for months. When Ra was taken by mouth it was eliminated twice as fast. M. RINGER.

Excretion of mercury by the gastric mucous membrane. C. C. LIEB AND G. M. GOODWIN. New York. *J. Am. Med. Assoc.* 64, 2041(1915).—Expts. with rabbits and cats, in which the esophagus was ligated to prevent the saliva from reaching the stomach, and the animals given 20 mg. HgCl_2 subcutaneously, showed the presence of Hg in the mucous membrane of the stomach after periods varying from 4 to 8 hrs. In one series of expts. the duodenum as well as the esophagus was tied off and Hg found after 4 hrs. The method employed in testing for the Hg was that of Vogel and Lee. Cf. C. A. 8, 1596.

L. W. RIGGS.

Isolation in the crystalline form of the compound containing iodine, which occurs in the thyroid. E. C. KENDALL. Rochester. Minn. *J. Am. Med. Assoc.* 64, 2042-3 (1915).—By an alk.-alc. hydrolysis the thyroid proteins are broken into many simpler constituents (cf. C. A. 9, 1625). These may be sepd. into 2 groups: (A) those insol. in acids; (B) those sol. in acids. From A a pure cryst. compd., containing 60% of I has been isolated. It appears to be diiododihydroxyindole. Group B contains I in some unknown form of combination. It is a mixt. containing amino-acid complexes and has a low mol. wt. Administration of A produces in the dog and in the human being a rapid increase in pulse rate and vigor, and increase in metabolism and nervous irritation. This physiologic activity is produced by the compd. containing I in all stages of purity up to and including its cryst. form. Given in excess, toxic symptoms are produced. The amt. of the I compd. required to produce toxic effects is exceedingly small. The I compd. plays an important role in the production of the symptoms of exophthalmic goiter. The constituents of group B, although containing I, produce no toxic symptoms, but in cases of cretinism, myxedema and certain skin conditions, they exert physiologic activity.

L. W. RIGGS.

Action of ether on the ductless gland system. G. MARCHETTI. *Riforma medica* 31, No. 24(1915); *J. Am. Med. Assoc.* 65, 370.—The administration of ether to cats by inhalation was followed immediately or after 2 hrs. by an increase of 40 to 50% in the epinephrine content of the suprarenal, which returned to normal after 24 hrs. There was also a less pronounced increase of epinephrine after the administration of ether by injection.

L. W. RIGGS.

Salicylic compounds and salicin (SHARP) 17. Phenazone, phenacetin and acetanilide (SHARP) 17.

12. FOODS.

W. D. BIGELOW.

The detection and determination of benzoic acid in animal foods. K. BAUMANN AND J. GROSSFELD. *Z. Nahr.-Genussm.* 29, 397-409, 465-72(1915).—A comparison of a number of qual. tests for benzoic acid showed the $(\text{C}_6\text{H}_5\text{CO}_2)_2\text{Fe}$ repptn. to be exceedingly delicate provided the soln. to be tested as well as the reagent is neutral, that an excess of reagent is avoided, and that other organic or inorganic salts, particularly CH_3COONa , are not present in large amts. These conditions can be attained by carefully adding weak NaOH to a soln. of the acid containing a trace of phenolphthalein until a slight pink color appears, the color being then discharged with a minute amt. of 5% CH_3COOH . Use neutral Fe alum soln. as a reagent. The Mohler test modified by v. d. Heide and Jacob was found to be sensitive to 0.1 mg. benzoic acid, while that of Jonescu failed to detect less than several mg. The Cu salt is also recommended for the detection of benzoic acid, giving a bright blue ppt. in neutral soln. Neutral CuSO_4 soln. is used for this purpose, the ppt. not being readily sol. in excess of the reagent. Milk (quant. detn.): treat 100 cc., which must not contain more

than 0.5 g. benzoic acid, with K_2CO_3 until a permanent red color is obtained in the presence of phenolphthalein, dil. to 200 cc., add 20 cc. of 20% $CaCl_2$ soln., heat on a steam bath for 15 min., cool, and filter through a dry filter. Measure 175 cc. of the filtrate into a 200 cc. flask, add a few drops of satd. $CuSO_4$ soln., and shake; then add 10 cc. of Na phosphotungstate soln. (20 g. $Na_2WO_4 \cdot 2H_2O$, 12 g. $Na_2HPO_4 \cdot 12H_2O$, one l. water), make up to vol. with 1:3 H_2SO_4 , and allow to stand overnight. Filter through dry paper, ext. 100 cc. of the filtrate with CCl_4 for 6 hrs., dil. the CCl_4 ext. with an equal vol. of neutral alc., and titrate with 0.1 *N* NaOH, using phenolph. as indicator. Fats (quant. detn.): warm 50 g. in a beaker until the fat is liquid, add 150 cc. of C_6H_6 , transfer the liquid to a separatory funnel, rinsing the beaker with ether, and shake the contents of the sep. funnel once with strong, warm K_2CO_3 soln. containing a little phenolph. If the red color is discharged, add more K_2CO_3 and shake again. Run the aq. layer from the sep. funnel into the beaker and wash the C_6H_6 -fat mixt. with several portions of warm water, adding these to the K_2CO_3 mixt. in the beaker. Then treat the contents of the beaker with 20 cc. of 20% $CaCl_2$ soln., add a few pieces of pumice and heat over a small flame until the odor of C_6H_6 disappears, transfer to a 200 cc. flask, add a soln. containing a few cg. of gelatin, cool, and make up to mark with water. Filter through a dry paper, transfer 175 cc. of the filtrate to a 200 cc. flask, add 10 cc. of the Na phosphotungstate soln. described above, and make up to vol. with 1:3 H_2SO_4 . After standing for several hrs. filter and det. benzoic acid in 100 cc. of the filtrate as given above. Meat products (quant. detn.): heat 100 g. of the meat in a beaker with 100 cc. of 5% NaOH until dissolved, transfer the hot mixt. to a separatory funnel, allow the fat to sep., and run the aq. layer into a 700 cc. flask. Rinse the beaker with a little water and add this together with about 50 cc. of C_6H_6 to the fat in the sep. funnel. Shake gently, allow to sep., and add the aq. layer to the contents of the flask. Wash the C_6H_6 -fat layer with a small amt. of water, adding this to the first aq. sepn. Render the combined aq. exts. slightly acid with H_2SO_4 , cool, underlie with an equal vol. of concd. H_2SO_4 , subject to steam distn., heating the mixt. to maintain const. vol., and collect 500 cc. of distillate. Add KOH to the distillate until it is slightly alk. to phenolphthalein, warm to dissolve the fatty acids, and then add dil. H_2SO_4 until the red color disappears but not enough to redden blue litmus paper. Evap. to 50 cc. in a porcelain dish, add 2 cc. of 20% $CaCl_2$ soln.; filter through a small paper, and wash the ppt. with a little hot water. Acidify the filtrate with H_2SO_4 and ext. the benzoic acid with CCl_4 by perforation, proceeding from this point as in the case of milk given above. Meat products (qual. test): dissolve 50 g. of meat in 100 cc. of hot 5% NaOH, treat with 40 cc. of 20% $CaCl_2$ soln., cool, filter, and reflux the filtrate with 25 cc. of concd. H_2SO_4 . Cool, filter, shake the filtrate with ether, and wash the ether layer with a little water. Fairly pure benzoic acid will be obtained upon evapn. of the ether. By these procedures excellent results can be obtained except in the case of substances, like cheese, containing large amts. of water-sol. fatty acids. A number of test analyses showing excellent results are given.

A. F. SEEKER.

Increase in the fat-free dry substance of milk from which the fat has been wholly or partially removed. GIACOMO TELLERA. *Boll. chim. farm.* 53, 358-65(1914).—T. has further analyzed the data obtained by Formenti regarding the fat-free dry substance of pure and watered milk from which the fat has been wholly or partially removed; he finds that the fat-free dry substance may be calcd. from the relation $r/(100 - g) = r'/100$ in which r is the original fat-free dry substance, g is the amt. of fat removed and r' is the fat-free dry substance of the milk after removal of fat. Assuming that 0.25 represents the max. error of technic (due to errors of observation, slight mechanical losses, slight increases in wt. due to oxidation, etc.) it is found that

only 22 of 206 samples of milk investigated by Formenti show an abnormal content of fat-free dry substance (i. e., where the abs. difference between the calcd. and observed values exceeds 0.25); 21 of these 22 samples were commercial and 8 of this no. were normal and showed abs. differences of 0.27-0.42 between the calcd. and observed values, while the other 13 samples were watered and showed differences of 0.27-0.42 with the exception of 2 of this no. for which the differences were 0.59 and 0.81, resp. (the remaining one of the 22 exceptions was an abnormal, non-commercial sample of pure milk, for which the contents of fat-free dry substance and fat were 8.62% and 3.40%, resp.). In each of the 22 exceptions noted above the observed value was greater than the calcd. value of fat-free dry substance.

H. S. PAINE.

Experimental data comparing the delicacy of different tests for hydrogen peroxide in milk. I. T. DARLINGTON. *J. Ind. Eng. Chem.* 7, 676(1915).—Comparative tests with the following reagents: starch, *p*-phenylenediamine, benzidine, titanous acid, vanadic acid. The tests were made on milk immediately after the addition of H_2O_2 and also 18 hrs. later. *p*-Phenylenediamine and benzidine gave the most delicate tests, the limits being 0.00075 g. H_2O_2 per 100 cc. milk. Practically all H_2O_2 is reduced after standing 18 hrs. except when the H_2O_2 content is 9 and 15%. I. M.

The analysis of frozen milks. L. PADE. *Ann. fals.* 8, 170-2(1915).—Cans of milk were frozen solid and then gradually melted, the melted portions being removed from time to time. Analyses of these portions showed a great variation in their compn. That melting first was the richest in solids, fat, ash, etc.

H. S. BAILEY.

Estimation of milk fat by the Kumagawa-Suto method. G. PALAZZOLO. *Industria lattiera e zootechnica* 12, 92(1914); through *Ann. chim. applicata* 3, 378-9(1915).—Expts. showed that the Kumagawa-Suto method gives slightly higher results than the Gottlieb-Röse method. The former is more exact, but the latter is more rapid and easier.

S. LEVY.

Farinaceous milks. GOBERT. *Ann. fals.* 8, 165-70(1915).—The Swiss Codex defines "Farinaceous Milks" (Malted Milk?) as preps. composed of a mixt. of dried milk and cereal or legume flour, the starch being so treated as to render it as sol. as possible. There should be at least 4% of fat present. The various methods of rendering the starch sol. and the properties which these preps. should possess are discussed. A detn. of the % of H_2O , fat, total sol. solids, reducing sugars, sucrose, casein, insol. solids, ash, N, and starch, together with the butyrefractometer reading and microscopic exam., should be made. From the results the % of milk, hydrolyzed and unhydrolyzed starch can be calcd. Figures for 5 samples of wheat flour and 4 of so-called "farinaceous milks," only one of which contained any appreciable quantity of milk fat, are given.

H. S. BAILEY.

Modifications of milk secretion of cows having a very prolonged period of lactation. E. GOLDOMI. *Industria lattiera e zootechnica* 13, 70(1915); through *Ann. chim. applicata* 3, 379(1915).—The milk of cows whose period of lactation was prolonged for about 1½ yrs., was less in quantity than ordinarily, but richer in solid substances. S. L.

Pasteurization of cream for butter-making. Iowa Expt. Sta., *Bull.* 156, 40 pp. (1914). **Part I. Effect on quality and chemical composition.** M. MORTENSEN, W. G. GAESSLER and W. H. COOPER. Pp. 1-26. **Part II. Bacteriological studies.** B. W. HAMMER. Pp. 27-40.—The following summary is given for Part I: "Pasteurization of either sweet or sour cream improves the flavor of the resulting butter. Vat pasteurization seems to be the most efficient method of sour cream pasteurization for improvement of flavor. The % of butter fat lost in the buttermilk when churning raw cream is slightly greater than with cream pasteurized while sweet. Reversed results were obtained when sour cream was pasteurized. The % of butter fat lost in

the buttermilk when churning cream pasteurized while sour by the holding method is greater than when churning cream pasteurized while sour by the flash method. The body of the resulting butter is slightly injured by pasteurizing sweet cream by the holding method. Butter manufd. from raw cream has higher moisture content than butter manufd. from cream pasteurized by the flash method. Prolonged heating of sour cream produced a higher moisture content in the resulting butter. The % protein content of the resulting butter is not influenced by the pasteurization of sweet cream, but is decreased by pasteurization of sour cream. Part II deals with comparative studies on pasteurization. The method of vat pasteurization, flash method and double pasteurization were considered. The flash and double methods were equally efficient.

B. E. B.

The influence of sugar beet feeding upon the composition of butter fat. J. BOES AND H. WEYLAND. *Z. Nahr.-Genussm.* 29, 473-5(1915).—A sample of butter obtained from a herd fed exclusively upon sugar beets showed the following analysis: water 14.79%, ash 0.062%, casein + lactose 1.28%, and acidity 3.87%. The butter fat gave: m. p. 33°, solidifying p. 23°, refract. read. (25°) 51, acidity 3.61, R.-M. no. 28.16, Polenske no. 6.16, sapon. no. 234.2, and I no. 24.22. A comparison of these with previously published figures is given.

A. F. SEEKER.

Apparent effect of acetic acid upon the constants of butter fat. C. BAHLMAN. *J. Ind. Eng. Chem.* 7, 680-1(1915).—A study of the cause of low results in the detn. of fat content of ice cream by the method of Lichtenburg (*C. A.* 7, 3624). It was found that fats sepd. in the presence of acetic acid retain this acid mechanically; the latter should be removed by drying at 90-95° for 1 hr. before the detn. of the fat constants.

ISADOR MILLER.

Determination of peanut oil in olive oil. R. LUND. *Tidskrift Kem. Farm. Terapi.* 12, 157-60(1915).—The acids from pure peanut oil crystallize out of the alc. soln. used in the Franz-Adler method (cf. *C. A.* 6, 2656; 7, 846) at 40-41°. For each successive tenth part of olive oil added to peanut oil the temp. of clouding in the alc. soln. becomes 39.3, 38, 36.6, 35.5, 33.8, 31.5, 29.2, 25.7, 19.8°. If no clouding takes place until after the temp. has dropped to 16° or less the peanut oil in the sample examd. is under 5%.

A. R. ROSE.

Tables for calculations in analysis of sugared solutions. N. VACCARONI. *Ann. Lab. chim. cent. delle Gabelle* 7, 253(1914); through *Ann. chim. applicata* 3, 374(1915).—Applicable especially to com. glucoses, condensed milks, and candies.

S. LEVY.

Baking without grain flour. WA. OSTWALD AND A. RIEDEL. *Chem. Ztg.* 39, 537-8(1915).—Results of expts. with potato and tapioca flours singly and mixed in equal proportions, to which was added potato flour paste, with baking powder or milk and yeast and a little sugar and salt, and, in 1 case, eggs. Potato flour and paste with milk and yeast gave the best results. Cf. Fornet, *C. A.* 9, 2406.

J. H. MOORE.

Shorts or middlings. A. MCGILL. Inland Revenue Dept., Ottawa, Canada, *Bull.* 311, 23 pp.(1915).—Analyses of 189 samples of cattle feed collected in Canada.

E. H.

Detection of rice husks in fodder-meal. E. COEN. *Ann. lab. chim. cent. delle Gabelle* 7, 105(1914); through *Ann. chim. applicata* 3, 372(1915).—The products of the grinding of wheat give an ash almost completely sol. in HCl, while the ash of rice husks is almost completely insol. Hence the detn. of the total ash and the part insol. in HCl gives a sure means of detecting rice husks in fodder or bran of wheat. Microscopic exam. will show the siliceous skeletons of the rice husks.

S. LEVY.

White pepper. A. MCGILL. Inland Rev. Dept., Ottawa, Canada, *Bull.* 314, 39 pp.(1915).—A report of results of the exam. of 387 samples collected throughout

Canada. Only 4.1% of the samples examd. were adulterated. Starch and flour were the chief adulterants found. E. J. C.

The official method for determining crude fiber as applied to cottonseed meal. C. K. FRANCIS. *J. Ind. Eng. Chem.* 7, 676-80(1915).—Slight modifications in procedure are suggested. A thorough investigation of filtering media has been carried out. Filter paper is the medium preferred as it is shown that there may be a loss of crude fiber when linen is used and that the results are apt to be too high with asbestos because the asbestos loses weight. ISADOR MILLER.

The use of "steriline." BORDAS. *Ann. fals.* 8, 182-8(1915).—"Steriline," a prepn. of NaOCl, is not approved by the Superior Counsel of Hygiene of France for use in preserving food. H. S. BAILEY.

Investigation of the Bömer method for detecting tallow in lard. J. PRESCHER. *Z. Nahr.-Genussm.* 29, 433-7(1915).—Fifty-eight fats of known character were examd. by both the Bömer (*C. A.* 8, 1174) and the Polenske (*C. A.* 2, 716) methods in order to ascertain their relative efficiency in detecting foreign fats in lard. In the case of 25 samples of adulterated lard only 3, containing, resp., 10, 20 and 30% of beef tallow, could be detected by the Polenske method, the others, some containing as much as 15% of beef tallow, giving negative tests. The Bömer method failed in only 2 cases, in which 5 and 10%, resp., of beef tallow were present. Eighteen samples of pure lard gave negative tests by the Bömer method, the Polenske procedure giving false indications of adulterations in 2 case. Hydrogenated vegetable oils give a positive Bömer test and can be distinguished from beef tallow by the phytosteryl acetate test. The Bömer method is to be preferred for simplicity and accuracy. A. F. SEEKER.

Use of aluminium in the food industries (TRILLAT) 16. Fermentation of table sirups (OWEN) 28.

U. S., 1,149,627, Aug. 10. S. H. BUNNELL. Desiccating milk, or other solns. The material is placed in a closed chamber and vapors are drawn off from the chamber to conc. and cool the material and the conc. product thus formed is then desiccated by heating in bulk and flowing over heated rolls.

U. S., 1,149,914, Aug. 10. F. W. HAUSERMANN. Stable food product from potatoes; prepared by boiling and mixing with an equal amt. of boiled rice, flavoring with spices, kneading and forming into strips with heated rollers.

U. S., 1,150,269, Aug. 17. S. M. HEULINGS. Pasteurizing milk by heating to 60-65° and holding at this temp. for some time, then heating for a shorter time to 70-80° and rapidly cooling.

U. S., 1,150,303, Aug. 17. E. M. POTTER. Chicory root is prepared for use in beverages by boiling with H₂O, rinsing after removing the ext., and drying and roasting. This treatment removes the bitter principle.

U. S., 1,150,607, Aug. 17. L. KLEINBREDD. Carob is treated with steam under pressure to remove butyric acid and 85 parts of the carob are then mixed with chestnuts 5, potato flour 5, saloop 2, fats 2, gum arabic 0.5 and vanilla or other flavoring 0.5 part.

U. S., 1,150,733, Aug. 17. H. BARNHARD. A powder for preparing beverages is formed by drying and roasting thin slices of the root of *Daucus carota*, until they become dark and brittle, and pulverizing. The drying requires about 20 min. at 38° and the roasting about 10 min. at 74°.

Brit., 8,865, Apr. 8, 1914. J. W. BAILEY. A porridge-like pudding is made

by boiling a mixt. of cracked wheat, raisins, arachis nut oil, milk, sugar, and salt, with water.

Brit., 9,024, Apr. 9, 1914. J. MILBURN. Preserving foodstuffs, beverages, etc., by the addition of a mixt. of salicylic acid, Na sulfocarbolate, sulfurous acid, or a sulfite, and benzoic or boric acid or a borate.

Brit., 9,491, Apr. 16, 1914. J. LEROUX. Coffee berries are formed into tablets, which readily break up in H_2O , by subjecting them, in molds, to the action of shocks which continue as pressure without recoil, *e. g.*, the action of a fly press. The berries are subjected to successive compressions in different directions.

EDWARD BARTOW.

Culture media employed for the bacteriological examination of water. I. The Schardinger-Dunham medium for testing for the presence of hydrogen sulfide-forming bacteria. E. M. CHAMOT AND H. W. REDFIELD. *J. Am. Chem. Soc.* 37, 1606-30 (1915); cf. *C. A.* 8, 2913.—To study the S.-D. medium (*J. Am. Chem. Soc.* 19, 591 (1897)), in which 3 factors may influence the growth of the bacteria (conc. of the peptone, conc. of the inorg. salt, reaction of the medium), Gibbs' triangular diagram was used. Filtered solns. of Kahlbaum's "Witte peptone" were used, the reaction of the medium being adjusted at 20°. An artificial sewage (0.02 g. fresh human feces shaken thoroughly in 1 l. H_2O and filtered through sterile cloth) was generally employed. From the numerous expts., reported in tables and a diagram, C. and R. conclude that: Regardless of the inorg. salts present and the acidity of the medium, concn. of 3-4% peptone in the final inoculated and incubated medium appears best for the most rapid and energetic production of H_2S ; the addition of beef broth increases the sensitiveness of the medium but not in proportion to the increased trouble and labor involved; if NaCl is added, not more than 1.5% must be used (more H_2S is obtained when NaCl is present); in 3% peptone media, 0.5-1.0% KCl is decidedly beneficial, giving quicker, better and far more uniform results than any other inorg. salt studied; positive results may be obtained in 18 hrs.; truly "clean" natural waters produce no H_2S in 72 hrs. while contaminated waters give much H_2S in 12-24 hrs.; feces of domestic animals contain bacteria capable of producing as much H_2S in a simple peptone medium as human feces; the large amts. of H_2S rapidly produced by sewage organisms appear not to be due primarily to members of the *B. coli* group; this group of H_2S -producing bacteria does not actively ferment carbohydrates, hence testing for their presence is of special value in polluted waters free of the *B. coli* group; H_2S is apparently more rapidly produced in waters containing mixed bacterial flora than by the isolated pure cultures alone. II. Lactose-peptone media. E. M. CHAMOT AND C. M. SHERWOOD. *Ibid* 1949-59.—The triangular diagram was used for the system of 4 components, concn. of nitrogenous material, of inorg. salts, of acid, and of carbohydrate; only one can be kept const. while the others are varied. The investigation was confined to bacteria of the *B. coli* group. Preliminary detns. showed that under the conditions obtaining in the prepn. and sterilization of the media the acidity was so low that no detectable inversion of the lactose occurred. In media prepd. from lactose, inorg. salt and Witte peptone alone, with the reaction unadjusted (*i. e.*, with a final acidity of 1-1.2% *N* HCl, due to the peptone), there was no perceptible change in acidity on sterilizing, but with meat and liver broths marked changes occurred on sterilization and subsequent standing. Tap H_2O gave more sensitive media than distd. H_2O . C. and S. studied the effect of variations in initial acidity, of lactose concn., of the presence of inorg. salts, of peptone concn. on the gas vol., of the size

of the fermentation tubes on the gas vol. and the comp. of the gas formed. They find that in H_2O contaminated with sewage, human and domestic animal feces and pure strains of the *B. coli* group the vol. of gas formed by lactose fermentation increases to a final max. with the concn. of the peptone, liver or meat ext.; the comp. of this gas depends on the concn. of the nitrogenous substance used (the analytical results will be published later); the addition of 0.5-1.0% KCl (and, to a less marked degree, of NaCl) appears to stimulate fermentation and assure more uniform results; nothing is gained by using the lactose in greater concn. than 1%; neutral media seem to yield slightly larger gas vols. than media slightly acid to phenolph., but media having a reaction of approx. 1% *N* HCl ferment considerably more rapidly and yield diagnostic results in several hrs. less time; the gas ratios of organisms of the *B. coli* group depend upon the concn. of the peptone or similar nitrogenous material; addition of meat infusion improves media of low peptone concn. but gives media whose reactions rapidly change; a very sensitive medium yielding uniform results and large gas vols. and changing but little on keeping consists of 3-4% peptone, 0.8% lactose, 0.6% KCl, with an acidity of 1% *N* HCl. III. Composition of the gases formed in lactose-peptone fermentation tubes. E. M. CHAMOT, C. M. SHERWOOD AND R. C. LOWARY. *Ibid* 2198-204.—Huge fermentation tubes, with a gas collecting tube of about 300 cc. capacity and a reservoir of about 600 cc. corresponding to the bulb of a standard fermentation tube, were used. In the gases formed, neither heavy hydrocarbons nor CO were detected in 100 cc. gas at any time. The vol. of gas increases rapidly with increasing concn. of peptone, meat or liver in lactose media up to 4% peptone but above 5% the increase is but slight. Below are the % of CO_2 and H, resp., in the gases obtained with media containing 1, 2, 3, 4, 5, 6, 8, 9 and 10% peptone: 26.9, 70.2; 34.2, 63.2; 37.7, 62.3; 38.0, 58.3; 39.0, 59.0; 39.5, 60.5; 39.8, 60.2; 39, 61.0; 40, 60. In the 1, 2, 4 and 5% peptone media were also obtained 2.9, 2.6, 2.7 and 2.0% not absorbed and considered as N. The variations in comp. in different runs with media prepd. at different times and inoculated with different sewage samples were smaller than anticipated. Dextrose media give gases of substantially the same comp. In only 3 cases was any evidence obtained of the presence of O, nor was any measurable vol. of CO_2 obtained after combustion, showing that only minute traces of CH_4 could have been formed, if any. The analyses were made, however, as soon as the max. fermentation was reached, *i. e.*, as soon as the gases ceased to increase in vol. (usually 20-6 hrs.). Since the passage from the closed tube to the bulb was relatively small (5 mm. in diam.), the growth in the fermentation tube may be properly considered as anaerobic. When varying vols. of pure sterile O (15-50 cc.) were introduced into the closed arm and the tubes, after inoculation with sewage, were incubated at 38° for 24-6 hrs. small amts. of CH_4 (0.2-0.4%) were obtained. The total vol. of gas formed, including the O, remained practically const., *i. e.*, the amt. of gas formed is proportional to the vol. of liquid in the closed arm. In the above expts. with 15, 42 and 50 cc. O, 4.23, 24.8 and 25.7 cc. O were recovered, while the % of CO_2 and H, corrected for the excess of O, were 42.3, 55.9; 42.4, 54.2; 41.3, 54.1, resp. (peptone, 3.5-4.0%), *i. e.*, a relatively enormous consumption of O by the bacteria does not materially affect the comp. of the gases formed, although excess of O seems to be followed by an increase in CO_2 and decrease in H; it does not increase the final acidity. The above results indicate that the "gas ratio" of a mixed sewage flora or of fecal bacteria will probably vary from $CO_2:H = 1:3$ with low to 1:1.15 with high peptone concns. Standard lactose media with 500 g. meat per l. and 1% peptone behave like media containing 1.5-2.0% peptone. With high peptone concns. to which meat had also been added, usually about 2% more CO_2 (and correspondingly less H) was obtained as compared with media containing no meat. "Enriching agents" (bile, bile salt, phenol) appear to affect neither the total vol. nor the comp. of the gases formed. Pure cultures of *B. coli* give results similar to those obtained with mixed sewage flora.

Determination of sulfates in water by benzidine hydrochloride. F. W. BRUCK-MILLER. *J. Ind. Eng. Chem.* 7, 600-2(1915); see C. A. 9, 1209. ISADOR MILLER.

The borderline in detecting a taste of potash liquors in drinking water. W. MARZAHN. *Mitt. kgl. Landesans. Wasserhygiene* 20, 37-57(1915).— $MgCl_2$ can be tasted in water when present in quantities of 168 mg. per l. The temp. of the water is of great importance in detecting the admixt. of foreign salts. Younger people perceive the taste more quickly than elderly people. Smokers are poor subjects for detecting a taste. •

ARTHUR LEDERER.

Prevention of corrosion and scale formation in steam boilers. G. C. JONES. *Chem. Trade J.* 57, 77-8, 101-2(1915); *J. Inst. Brewing* 21, 422-35(1915).—The detn. of H^+ and OH^- concn. by the Sørensen method of titrating is described and the Walker and Kay method of expressing the acidity or alkalinity is advocated. The practical methods of treating H_2O for boiler purposes are outlined and the relative value of such methods is discussed critically.

W. T. HALL.

Severe boiler corrosions. A. HEINZELMAN. *Der Klein u. Mittelbrauer* 1914, [2] 238; *Chem. Tech. Rept.* 38, 376(1914).—A feed water containing 30 p. p. m. of silicates, an equal amt. of nitrates and a moderate amt. of Cl and reacting alk., was uncorrosive when used in boilers operated at pressures of 4 atms. In boilers operated at 10-12 atms. it caused severe corrosion and samples tested acid. Hydrolysis at the higher pressure liberated silicic acid from Fe silicates; this in turn liberated HCl and HNO_3 . The trouble was remedied by the addition of Na_2CO_3 . H. notes that a method used in powder mills for estg. HNO_3 in nitrates depends upon heating the sample with a weighed amt. of H_2SiO_3 .

H. L. OLIN.

Boiler preservatives. W. KOHEN. *Chem. Ztg.* 39, 121-2(1915).—K. reports the following analyses of 3 preps. with same trade name purchased from 3 different firms, each sample being different from that furnished previously under same name:

	A.	B.	C.
Total ash.....	15.09%	3.88%	12.97%
C_6H_6 insol. solid matter.....	62.66	4.25	25.24
Ash in solid matter.....	21.25	0.35	9.69
SiO_2	2.67	..	2.08
Al_2O_3	7.12	..	...
Fe_2O_3	...	..	1.4

The insol. matter in A contained metallic Al. On distn. A yielded between 70° and 130° about 6%; B from 60° to 100°, 9%; 100-150°, 12%; C from 75 to 100°, 6.6%; 100-150°, 4%; 150-200°, 8.6%. The material is used as a coating to protect boilers against corrosion and scale formation. K. warns against the use of any prepn. of unknown comp.

The International Joint Commission's investigation of sewage pollution of boundary waters. A. J. McLAUGHLIN. *Am. J. Pub. Health* 5, 555-9(1915); cf. *C. A.* 8, 1317, 2914.—M. discusses the technic of exam. and describes an anaerobic organism which ferments lactose bile, resembles *B. welchii* and generally appeared when material from the gas tubes was transplanted into hot agar. M. thinks that presumptive test (gas in lactose bile) alone for *B. coli* in certain waters is somewhat misleading unless a confirmatory test is made. J. GAUB.

Clarifying waste water and the removal of slimes at blast furnace plants. EMIL OPDERBECK. *Stahl u. Eisen* 35, 281-7, 336-46(1915).—The German laws forbid dumping slime-bearing water into the streams. The paper describes and illustrates methods for clarifying such waters and the disposal of the slime.

CARLE R. HAYWARD.

The purification of city waste waters in Germany by natural, biological methods. J. KÖNIG AND H. LACOUR. *Landw. Jahrb.* 47, 477-571(1914).—A detailed report giving statistics and observations as well as the results of experiments on the purification of waste waters from numerous cities in Germany. The advantages of the irrigation process whereby the fertilizer products of the water are utilized are pointed out and the authors suggest that this method be used wherever the conditions are suitable. A bibliography is appended. C. F. MILLER.

Biological observations on sewage purification plants. HERM. HELFER. *Mitt. kgl. Landesans. Wasserhyg.* 20, 70-112(1915).—The organisms of various purification plants near Berlin were thoroughly examined and tabulated. The lumbricoides, which are present in biologic filters in enormous numbers, undoubtedly participate largely in the decompn. of sewage matter. Spiders and sewage flies were also noted in very large numbers around the filters in the warm season. These larger organisms again attract birds. The microscopic fauna and flora remain substantially the same in the

coldest and warmest weather; the macroscopic organisms, however, are greatly influenced by the season.

ARTHUR LEDERER.

Biologic-microscopic investigation of sewage disposal on the coast. J. WILHELM. *Mitt. kgl. Landesans. Wasserhyg.* 20, 113-204(1915).—W. investigated the effect of the discharge of sewage effluents upon the sea water in various places along the northern coast of Germany. The plankton life was thoroughly examined. Such an exam. answers the question whether the water is polluted or not. *Chlamydothrix longissima* can serve as a typical indicator of salt water pollution. Self-purification is more active in fresh than in salt water. Suspended matter settles more quickly in salt water, resulting in sludge deposits near the sewage outlet. These deposits are apt to create a nuisance. Oysters are likely to become infected in such waters. The salt-water fauna shows a greater variety than the fresh-water fauna.

ARTHUR LEDERER.

Brooklyn sewage-aeration and activated-sludge experiments. E. J. FORT. *Eng. News* 74, 214-7(1915).—Studies have been made of sewage aeration by (1) compressed air passed upward from a pipe grid and shallow gravel bed through sewage passing downward in a deep tank containing 9 horizontal disk deflectors. The first expts. with plain aeration of sewage in the aerating tank were not very encouraging, an air supply of 0.75 vol. per vol. of sewage with 2 hrs. retention being insufficient to produce any marked improvement on crude sewage. The second expt. was carried on in an aerated contact bed. The improvement was very marked, the 24 hr. samples being almost of drinking water quality. The third expt. dealt with the activated-sludge process and was carried on in the same tank as expt. (1). The continuous flow and fill-and-draw plan was tried alternatively. 24 hrs. aeration resulted in 100% relative stability.

ARTHUR LEDERER.

Operating records of Atlanta sewage treatment plant. CHARLES C. HOMMON. *Eng. Record* 72, 4-7(1915).—The Proctor Creek plant consists of a sand trap, grit chambers, Imhoff tanks, a revolving screen, sprinkling filters, and sludge-drying beds. The preliminary bar screens remove about 30 lbs. wet screenings per mil. gal., which is disposed of by burying. The grit chambers remove about 0.3 cu. yd. of sand per mil. gal. of sewage treated. About 33 lbs. skimmings per mil. gal. accumulated on the settling chambers of the Imhoff tanks. Troubles with scum and foaming were overcome by withdrawing part of the sludge in the tanks. The sludge is removed from the tanks in small amts. every 2 weeks during the warm weather, thereby making it unnecessary to remove sludge in winter. It was found impracticable to use the Weand revolving screen on the Imhoff tank effluents. The filters were operated at a net rate of 2 mil. gal. per acre per day. Clogging was noticed during the winter months. Unloading took place in the spring, giving the effluent a dirty appearance. The effluents from the filters have a high relative stability and the nuisance which formally existed in Proctor Creek has been eradicated. Cost of treatment was \$3.93 per mil. gal. exclusive of interest on investment and depreciation.

FRANK BACHMANN.

Inquiry blank of the Kgl. Landesanstalt für Wasserhygiene regarding sewerage, sewage purification and disposal. ANON. *Mitt. kgl. Landesans. Wasserhyg.* 20, 1-11(1915).

ARTHUR LEDERER.

Expert opinion of the Kgl. Landesanstalt für Wasserhygiene on the experimental sewage purification plant of Karlsruhe. A. SCHIELE AND R. WELDERT. *Mitt. kgl. Landesans. Wasserhyg.* 20, 12-36(1915).—The plant consists of 2 screens of 2-mm. mesh. The screens are of the Riensch-Wurl and Geiger type. The Wurl type proved to be the more efficient and satisfactory.

ARTHUR LEDERER.

Sewage testing station at Decatur, Ill. LANGDON PEARSE. *Ill. Soc. Engr. and Surveyors* 1915; *Eng. News* 73, 555(1915); see C. A. 9, 1523.

Brit., 9,031, Apr. 9, 1914. R. FREIBERR VON WALTHER. Removing oxygen from water by passing it over, or filtering it through, easily oxidizable metals or alloys, such as Fe, Mn, Al, Zn, or Cu, either in their normal condition or after the metals have been purified by treatment with acids or have been "rendered active." Hydroxides produced are retained by filtration or periodically removed by spraying, and dissolved Fe, e. g., FeO, by filtering in contact with CaCO₃ or permutite. Oxide forming a coating on the metals may be removed by treatment with acids.

Brit., 9,341, Apr. 15, 1914. R. NÜBLING and A. KRAUSS. Treating sewage sludge, after preliminary drying, by distg. it in retorts heated by the hot waste gases after use in heating gas retorts.

Brit., 9,396, Apr. 16, 1914. C. HAYTHORPE. The efficiency of feed-water purifiers is increased by means of elec. currents generated by connecting various parts such as Zn partitions and the walls by strips of a dissimilar metal such as Cu.

15. SOILS AND FERTILIZERS.

R. O. E. DAVIS.

Amino-acid nitrogen of the soil and the chemical groups of amino acids in the hydrolyzed soil and their humic acids. R. S. POTTER and R. S. SNYDER. *J. Am. Chem. Soc.* 37, 2219-27(1915); cf. Lathrop, C. A. 9, 501, 948.—This work was under-

taken to correlate, if possible, the amts. of the various chem. groups of NH_2 acids in the soil with its humic acid, and of these groups in the soil and its humic acid with the kind of org. fertilizer previously applied to the soil and with similar groups in pure proteins, and finally to compare the amts. of NH_2 -acid N as such in the soil with that found by hydrolysis. P. and S. find that the amt. of N pptd. from a neutralized alkali ext. of soil varies qual. inversely with the strength of the acid; the amt. of humic N (found by the Van Slyke method) extd. by dil. alkali from the soil is very high as compared with the amts. in proteins; dil. alkali does not ext. any typical class of org. compds. from the soil; the amt. of NH_2 -acid and peptide N found in the soil is very small as compared with the amts. of NH_2 acids formed by hydrolysis. CHAS. A. ROUILLER.

Analyses of Nova Scotian soils. L. C. HARLOW. Normal Coll., Truro, N. S. *Trans. Nova Scotian Inst. Sci.* 13, 332-46(1913-14).—A large number of analyses has been made of the soils of Nova Scotia. The results thus far obtained show that although these soils have a good supply of potash it is only slightly available; that the phosphoric acid, which is present in small amts., is about $\frac{1}{2}$ available and hence soon used; that, while volatile matter is quite high, it is deficient in N, and that lime is very deficient in many soils. H. JERMAIN CREIGHTON.

Fallow land, its physiology, farms, purpose, significance and distribution formerly and now. A critical study. WILLY MAKKUS. *Landw. Jahrb.* 47, 673-718(1914).—The author points out, citing the literature, how weathering, chem. decomp., oxidation and other favorable changes brought about by natural forces or agents, come into play to a much greater extent in a fallow soil than in one under cultivation or in one neglected entirely. C. F. MILLER.

The effect of arsenite of soda on the soil. W. T. MCGEORGE. Hawaii Agr. Expt. Sta., *Press Bull.* 50, 16 pp.(1915).—The use of either Na_2AsO_3 or Na_2HAsO_3 as a spray for killing weeds is discussed. The poison is assimilated by the plants as shown by analysis. It has a deflocculating action on the soil. It exercised a variable influence upon soil bacteria, depending upon the type of soil. The arsenite is strongly fixed by the soil and is extremely hard to leach out, accumulating therefore in the top zone (first 4 in.). B. E. B.

A municipal fertilizer plant at Los Angeles, Cal. BURT A. HEINLY. *Eng. News* 73, 1063-4(1915).—This plant permits a compost of manure, lime and wood ashes. 10,000 cu. yds. a year are made at a cost of \$1.38 per cu. yd. L. PRARSE.

The composition and value of farm manures. O. F. JENSEN. Mich. Agr. Expt. Sta., *Circ.* 25, 7 pp.(1915).—J. gives the av. compn. of different manures in lbs. per ton; the variation in quantity and compn. of manure caused by feed; fertilizing constituents and their value in one ton of feeding stuffs; value of fertilizing constituents in one ton of manure from different animals; location of fertilizing elements in the excrement of the cow and the horse; amt. and value of the voidings of farm animals in 24 hrs.; and, finally, the amt. and value of manure produced in one year. B. E. B.

U. S., 1,149,390, Aug. 10. C. N. MERIWETHER. Phosphate fertilizer is made by mixing 10 parts of Fe in small pieces with 90 parts of pulverized phosphatic limestone, fusing the mixt., adding K compds., pulverizing the product and removing any excess of Fe from it.

U. S., 1,150,815, Aug. 17. C. W. DRURY. A fertilizer from feldspar is made by fusion of a mixt. of feldspar 50, CaO 16.8 and FeO 13.5 parts.

16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

Classification of alcoholic liquors. EUG. ROUX. *Ann. fals.* 8, 189-95(1915).—A discussion of the meaning of the terms applied in France to various alcoholic beverages, and typical analyses of 50 different liquors. H. S. BAILEY.

The detection of citric acid in wine. E. BAIER AND P. W. NEUMANN. *Z. Nahr.-Genussm.* 29, 410-1(1915).—B. and N. have extended the Denigès test for citric acid in order to identify the ppt. obtained. Neutralize 25 cc. of wine with NaOH and render distinctly acid to litmus with acetic acid. Then add 3 g. of pure blood charcoal (free from CaCO_3), allow to stand with frequent shaking for 10 min., and filter. To 10 cc. of the clear filtrate add 1 cc. of Denigès' reagent, heat to boiling and, if a ppt. appears, filter. Then add 1% KMnO_4 soln. drop by drop until Mn oxides begin to sep. Remove these by adding a drop or two of H_2O_2 . A flocculent white ppt. indicates citric acid. To identify this ppt. as the Hg salt of acetonedicarboxylic acid centrifuge the mixt., remove the liquid by decantation, transfer the ppt. to a small filter, and wash with a little cold water. Dissolve the ppt. in 2-3 cc. of 10% NaCl soln., passing this through the filter several times to insure complete soln. To this soln. add a drop or two of weak FeCl_3 soln. (1 pt. 10% FeCl_3 and 10 pts. water), the formation of a raspberry-red color confirming the presence of acetonedicarboxylic acid. A. F. SEEKER.

Detection of small quantities of oxalic acid in wine. HANS KREIS AND W. I. BARAGIOLA. *Schweiz. Apoth. Ztg.* 53, 397-400(1915).—To 50 cc. of wine add, cold, 2.5 cc. of a 5% CaCl_2 soln., 2.5 cc. of glacial AcOH, 5 cc. of a cold satd. soln. of NaOAc (cf. C. A. 8, 2215), allow to stand 24 hrs. On shaking, Ca tartrate adheres to the bottom while CaC_2O_4 becomes suspended. Centrifuge, then rinse the ppt. with the aid of the clear liquid into a small centrifuge tube whose lower end is about 2 mm. wide, and centrifuge again. This process will yield an amt. of CaC_2O_4 crystals sufficient for microscopical identification if only 0.001% of $\text{H}_2\text{C}_2\text{O}_4$ is present in the wine. The crystals are uniformly characteristic plates, about 1×3 ; or, heat 50 cc. wine to boiling, add 2-3 cc. of 5% CaCl_2 and NH_4OH to distinct alk. reaction. Add at once while boiling 50% AcOH to slight acidity, cool, centrifuge, and exam. the residue microscopically. This detects 0.002% $\text{H}_2\text{C}_2\text{O}_4$. CaCl_2 is used so as to lessen the solubility of CaC_2O_4 . It is notably sol. in presence of $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$ in the wine, also of SO_2 . No $\text{H}_2\text{C}_2\text{O}_4$ was found in 50 wines of known purity and 25 others, showing that CaC_2O_4 crystals in the cells of the grape do not pass into the wine. The presence of $\text{H}_2\text{C}_2\text{O}_4$ is due to manipulation to reduce the amt. of Ca. S. WALDBOTT.

Determination of sulfurous acid in wine. L. FERRÉ. *Ann. chim. anal.* 20, 151-5 (1915).—*Principle of Method:* SO_2 is distd. off by means of a current of CO_2 and received in a standard soln. of I (1 cc. corresponding to 1 mg. SO_2). To the distg. flask is connected a condenser to make sure that only CO_2 and SO_2 pass through the I soln. The CO_2 coming from the I-absorption bulb is passed through a 2nd bulb contg. a definite quantity of $\text{Na}_2\text{S}_2\text{O}_3$ soln. of a concn. equiv. to that of the I soln. *Procedure.* (A) *Total SO_2 :* Fill 40 cc. I soln. into a Strauss-Wurtz absorption bulb and 5 cc. $\text{Na}_2\text{S}_2\text{O}_3$ soln. in a 2nd and similar bulb, connect these two bulbs, avoiding contact with rubber tubing, and connect this absorption train with a condenser fitted to a distn. flask. Into the latter introduce 100 cc. wine and 2 cc. sirupy H_3PO_4 , pass a slow CO_2 current through the whole arrangement, heat (after expelling air) and keep gently boiling for 0.5 hr., continuing passing CO_2 through the app. The I and $\text{Na}_2\text{S}_2\text{O}_3$ in the absorption bulbs are then united in a beaker and the unconsumed I detd. by titration with $\text{Na}_2\text{S}_2\text{O}_3$ soln. (1 cc. corresponding to 1 mg. SO_2). If N cc. more $\text{Na}_2\text{S}_2\text{O}_3$ were consumed, then the total $\text{SO}_2 = 10 [40 - (N + 5)]$ mg. per l. (B) *Combined*

SO₂: For this purpose Mathieu-Billon's method was rendered volumetric. To 100 cc. wine are added as many cc. of I soln. as necessary to oxidize the total SO₂ and then the same quantity of an equivalent Na₂AsO₃ soln. After this prepn. the combined SO₂ is detd. in exactly the same way as the total SO₂ under (A). (C) **Free SO₂:** This is found by difference. The results with this procedure are compared with those obtained by Ripper's, Mathieu-Billon's and Haas's methods and found to be highly satisfactory. L. W. HAAS.

New method of determination of hydrocyanic acid and benzaldehyde in cherry brandy. J. GOLSE. *J. pharm. chim.* 12, 44-56(1915).—G.'s method was worked out to obviate the several sources of errors in the official process. Put 200 cc. of "kirsch," with 1 cc. of NaOH (d. 1.32-1.36), into a 500 cc. flask connected with an efficient condenser. Distil very slowly to avoid loss by foaming, collect 175 cc. of distillate, which contains part of the HCN having escaped fixation by NaOH, and all of the benzaldehyde. Cool the flask, apply a 55 cc. receiver containing 5 cc. NH₄OH, add to the contents of the flask through a separatory funnel, 50 cc. of dil. H₂SO₄ (1:10) and again distil very slowly, collecting 55 cc. This contains the bulk of the HCN originally present. To the 175 cc. of first distillate, add 5 cc. of phenylhydrazine bisulfite reagent (cryst. AcONa 10 g., glacial AcOH 5 cc., H₂O 100 cc.; 200 cc. of this mixt. + 3 cc. glacial AcOH + 1 cc. C₆H₅NHNH₂ (liquefied), + 1 cc. NaHSO₃ soln.) and distil again over a flame until 50 cc. are collected, and another fraction of 50 cc. to 75 cc. according to the % of EtOH present. Join these fractions to the above 55 cc. distillate. Replace the flame by boiling water bath, always continuing to cool, but preventing entry of air. When the pptd. hydrazone has collected (in 1 or 2 hrs.), cool and filter, wash with H₂O, drain and dissolve the ppt. with 10 cc. of abs. EtOH, washing twice with 10 cc. Et₂O. Evap. in a tared dish *in vacuo* and then weigh. The weight of the hydrazone times 2.7 gives wt. of benzaldehyde per liter of "kirsch." The HCN soln. is treated with 1 cc. of 10% KI, then titrated with 0.05 N AgNO₃ to opalescence. The number of cc. times 13.5 gives mg. of HCN per liter of "kirsch." Detn. of % of EtOH, mg. of HCN per liter and mg. of benzaldehyde per liter in 3 authentic samples gave the following results: (I) 48.8, 23.6, 30.2; (II) 50, 35.8, 37.3; (III) 50, 17.6, 29.7. In 3 doubtful samples, the corresponding results were: (IV) 48, 24.3, 108; (V) 48.5, 8.1, 73.4; (VI) 48.7, 18.9, 52.9. Previously recorded analyses based on the official method are untrustworthy. S. WALDBOTT.

The use of raw sugar in Austrian breweries. E. WEINWURM. Brunn. *Chem. Ztg.* 39, 601(1915).—Sugar may replace as much as 30% of the malt with satisfactory results. J. H. MOORE.

Examination of hops. E. MOUFANG. Kirm a.d. Nahe. *Allgem. Z. Bierbrau.-Malzfabrikation* 43, 227-31(1915).—Various samples of hops were first extd. with CHCl₃ and subsequently with water and the exts. examd. separately as to their phys. and chem. properties. The results led to the conclusion that for the practice of hopping beer worts it is suitable to separate the extractive substances of hops by water extn. into a readily sol. part (= A) and a difficultly sol. part (= B). Part A, since it plays only a minor role as carrier of hop-bitter and flavor but possesses a strong protein-pptg. power, ought to be added to the boiling wort after Part B (which eventually has been modified by boiling under pressure) has yielded its ext. to the wort as completely as possible. If worked in this manner the undesired darkening of wort during hopping may be eliminated, for Part A was recognized as the carrier of the substances that cause the darkening. L. W. HAAS.

Preservation of potato-slop by acidification with pure culture lactic acid. WILHELM VÖLTZ. *Z. Spiritusind.* 38, 255-6(1915).—The hop slop is discharged into water-proof pits and 0.5% sugar or the corresponding quantity of other saccharine material

(molasses, sugar beets, sweet potato-mash), previously sterilized by cooking, incorporated. After cooling the mixt. to 50° or below, it is best inoculated with 0.5% of a mixed culture of *Bacillus delbrücki* and *B. cucumeris fermentali*. In 2 to 3 days the max. acidity is obtained. To protect the acidified slop from contact with air, it is covered with a layer of oil 1 cm. thick. In an analogous way sugar-beet mash may be preserved. As a medium for the lactic bacteria, for which rye grist is unsuitable, a mixt. of 20-25% of grated sugar beets and 75-80% water may be used or sweet potato-mash of corresponding concn.

L. W. HAAS.

Losses of nutritive substances in rye-distillery materials. WILHELM VÖLTZ. *Z. Spiritusind.* 38, 245-6(1915).—Expts. on omnivora and ruminantia show that the working up of rye (and auxiliary material) for alc. implies a loss of 4% of total digestible nutritive substances for the latter as against 15% for the former over the raw material.

L. W. HAAS.

The caramel malt question. FR. LOWITZ. *Allgem. Brau.-Hopfen-Ztg.* 55, 823(1915).—A short review of the theory and technic of the prepn. of caramel malt.

L. W. HAAS.

The use of aluminium in the food industries. A. TRILLAT. *Bull. soc. encour. ind. nat.* 122, 555-74(1915).—A discussion of the properties of the metal with special reference to its adaptability for use in the distilling, brewing, and dairy industries.

H. L. OLIN.

Utilization of waste sulfite liquors (LANDMARK) (RINMAN) 23. Peroxidase in beer yeast (BACH) 11A.

U. S., 1,149,700, Aug. 10. A. P. STITZEL. A non-alcoholic beverage is made by removing the alc. from mashed and fermented wort by distn., flavoring the dealcoholized beer by mixing with hops or ginger and then cooling, settling, filtering and carbonating.

U. S., 1,149,704, Aug. 10. R. WAHL. Beer is flavored by mixing with it a hop ext. prepd. by treating hops with 20 times their wt. or less of a 1% soln. of NaOH at about 82° to ext. the hop-bitter acids and distribute them in colloidal form in the beer. The natural acid of the latter neutralizes the NaOH of the ext.

17. PHARMACEUTICAL CHEMISTRY.

M. I. WILBERT.

The analysis of essential oils. ANON. *Perf. Essent. Oil Record, Year Book 1915*, 8-15.—A general discussion including a brief outline of methods usually adopted in the exam. of essential oils (detn. of phys. constants, chem. tests, detection of adulteration, etc.).

E. J. C.

The solubility of water in essential oils. J. C. UMNEY AND S. W. BUNKER. *Perf. Essent. Oil Record, Year Book 1915*, 7.—These expts. were conducted to det. the amt. of water occurring in com. essential oils, the influence of this water on their keeping qualities and the relation between the chem. nature of the constituents of oils and the solubility of water in them. Oils representing the following groups were examd.: terpenes, alcs., aldehydes, phenols, esters, lactones and ketones. The phys. constants of these oils were detd. and the proportion of water that could be absorbed was calcd. from the rise in refractive index after drying. From the tabulated results the authors conclude: (1) Those essential oils which consist almost entirely of terpenes, of which oils of nutmeg, lemon, orange and juniper are types, are incapable of dissolving water to any appreciable extent. (2) Those essential oils whose chief constituent is an

oxygenated compd. or other terpene deriv., dissolve water in general to the extent of 0.5%, and in such oils the solubility of water is independent of the chem. nature of the chief constituent. (3) Higher solubility is observed in the case of Turkish geranium and Java citronella, but the lactone type, *e. g.*, eucalyptus, and the ketone type, *e. g.*, caraway, appear to be almost incapable of dissolving water. (4) None of the results obtained justifies the statement, which has frequently been made, that santal oil is capable of dissolving from 1 to 2% of water, and, in fact, it appears that it must be regarded as possessing a lower solvent power than the average. Even the small quantity of water which is found to occur can and does cause considerable inconvenience in the blending of oils. There is no doubt that the presence of water interferes with their keeping properties.

R. J. C.

The chemistry of the British pharmacopeia, 1914. CHARLES H. LA WALL. *Am. J. Pharm.* 87, 368-73(1915).—A review.

W. G. GAESSLER.

New way to extract lemon oil. LIOTTA. Catania, Italy. *Am. Perfumer* 10, 34(1915).—A new process which is said not to affect the oil in any way, such, *e. g.*, as causing changes in the properties and odor of the essence, is carried out as follows: the lemons are mashed in a large receptacle and an acid, the nature of which is kept secret, is added. This acid causes the essential oil to sep. and rise to the surface; it is then drawn off. A chem. reagent, that liberates the acid and permits its recovery, is then added to the acid mixt. The residue, consisting of lemon juice, pulp and peel, and foreign matter, is then sold to citrate manufacturers. The new process will save about 2.5% more oil than the old hand process; the cost of extn. is 2.3 c. per 1000 lemons and the time required 22 mins. Present methods used in Italy and France are discussed.

The manufacture of synthetic perfumes. JUSTIN DUPONT. *Bull. soc. encour. ind. nat.* 122, 476-91(1915).—An address reviewing the status of the industry.

H. L. OLIN.

Determination of methoxyl in beechwood tar. J. SUREDA BLANES AND ADOLFO GONZÁLEZ. *Anales soc. españ. fis. quim.* 13, 158-60(1915).—Inasmuch as the com. and therapeutic value of beechwood creosote is principally due to the guaiacol content B. and G. propose the detn. of methoxyl by the Zeisel method as an index of its quality. The Me of the MeO group is transformed by the action of HI into MeI which, being quite volatile, is passed through an alc. soln. of AgNO₃ with consequent formation of the compd. AgI.2AgNO₃; the latter loses its content of AgNO₃ when washed with H₂O and the wt. of MeO may then be calcd. from the wt. of the dried AgI. The Zeisel and Fanto app. was employed. The MeO content obtained represented the sum of the wts. of the MeO groups of the guaiacol, creosol and methylcreosol present in the creosote. Since mineral pitch does not contain a MeO group, sophistication of beechwood tar with this pitch may be readily detected by detn. of the MeO content. The distn. of guaiacol from beechwood tar may also be detected in the same way. Data

for n , b. p. and MeO content of a no. of samples of beechwood tar and mineral pitch are given.

H. S. PAINE.

Displacement curves of some organic bases and application to the determination of some alkaloids. R. GOUBAU. Univ. Ghent. *Bull. sci. acad. roy. belg.* 1914, 63-90.

—G. has applied the displacement curve of a base (*i. e.*, the curve which represents the variation of elec. cond. of a soln. of a salt of the given base resulting from the addition of increasing amts. of a base capable of displacing the 1st base) to the detn. of alkaloids. The exptl. procedure usually consisted in adding a known amt. of HCl to a known wt. of the weak base so that the soln. (aq. or alc. or both) contained an excess of acid; the cond. was then measured at a known temp. and also after successive additions of 0.1 cc. N (or 0.1 N) NaOH. The curve representing the variation in cond. usually consisted of 3 portions, a curve of neutralization, a curve of displacement and a portion which represents the increase in cond. corresponding to the addition of an excess of a strong base. The curve of neutralization was rectilinear, descending from left to right (conds. as ordinates and vols. of added NaOH soln. as abscissas); its direction depended especially on the nature of the acid present in excess in the soln. and on the nature of the strong base used for neutralization. The curve of displacement ascended from left to right when the velocity of migration of the cation of the strong base was greater than the velocity of migration of the cation of the weak base. This curve was horizontal when the velocities of migration of the 2 cations were equal; it descended from left to right when the velocity of migration of the cation of the weak base was greater than the velocity of migration of the cation of the strong base. The curve of displacement showed 1, 2 or 3 points of inflexion in case the base was di-, tri- or tetraacid, resp.; these points were not always distinct. The 3rd portion of the curve (which represents the increase in cond. corresponding to the addition of excess of a strong base) was rectilinear in case too high concns. were not employed; it was necessarily ascending from left to right. The angle formed by the curve of neutralization and the curve of displacement was the more distinct the less the degree of hydrolysis of the organic salt; this angle was not perceptible in the case of complete hydrolysis. The angle formed by the curve of displacement and the 3rd portion of the cond. curve was the more distinct the weaker the organic base. Tabulated data and cond. curves for a number of alkaloids are given. Cocaine may be detd. when present in amts. as small as 0.01 g. Atropine may be detd. with precision in pharmaceutical preps. of belladonna, provided the foreign substances (resins, chlorophyll, etc.) present in these preps. be first removed from the acid soln. of atropine by extrn. with Et_2O or CHCl_3 ; resins cause erroneous results even in the presence of large amts. of alc. Homatropine and coniine may be readily detd. by this method; the fact that the angle formed by the displacement curve and the 3rd portion of the cond. curve is quite obtuse indicates that coniine is a strong base with salts which are only slightly hydrolyzed. The cond. curve for nicotine was ill defined and difficult of interpretation. Aconitine may be accurately detd. in official preps. of aconite provided all resins are first extrd. by Et_2O . The points of inflexion of the cond. curve for pilocarpine are very distinct and the method yields accurate results; detn. of pilocarpine may be made in quite dil. solns. Measurements with morphine-HCl and morphine-AcOH yielded cond. curves which were composed of 3 ascending portions, *i. e.*, a portion AB corresponding to the displacement of morphine, a portion BC corresponding to the formation of Na morphinate (*i. e.*, a curve of the neutralization of a weak acid by a strong base) and a portion CD corresponding to the addition of an excess of a strong base; a 4th portion EA corresponding to the neutralization of excess of acid or base was also observed. Morphine may, therefore, be detd. in an alk. soln. of the morphinate (provided other alkaloids or other interfering substances are absent) or an acid soln. of a salt (acetate or

hydrochloride) of morphine. It is preferable to use an aq. soln. with no alc. present; an amt. as small as 0.01 g. morphine-HCl may be detd. with great precision. Codeine may be readily detd. by this method. In measurements with quinine, cinchonine, cinchonidine and quinidine, either individually or in mixt., it was impossible to obtain a distinct 1st inflexion point (end of the neutralization of the excess of acid) in the cond. curve. This was due to the pronounced hydrolysis of the salts of these alkaloids; the last inflexion point was always quite distinct. It is, therefore, not possible to det. the cinchona alkaloids by means of the displacement curves. The total amt. of acid present in a salt of 1 of these alkaloids may be detd., however, from the elec. cond. The first 3 of the 4 portions of the cond. curves of these alkaloids were replaced by a continuous curve in which it was not possible to distinguish a point of inflexion. Strychnine and brucine may both be detd. with considerable accuracy by this method; the fat which is present in large amt. in nux vomica should first be removed by Et_2O from pharmaceutical preps. in case it is desired to det. strychnine and brucine in the latter by this procedure.

H. S. PAINE.

Use of iron cacodylate (preparation of ferrous cacodylate). A. C. BARBANO. Turin. *Giorn. farm. chim.* 63, 145-9(1914).—A prepn. compounded from the following formula of Piccaluga is extensively used with good results in the region around Alba, Italy, in the treatment of various forms of anemia, chlorosis, etc.: 1 g. Fe''' cacodylate, 2 g. tincture of nux vomica, 100 g. distd. H_2O . B. proposes to improve this formula by substituting Fe'' cacodylate for Fe''' cacodylate; inasmuch as the former is not readily available in the solid state, the following procedure is recommended. Slake 17.00 g. pure CaO (from marble) with a small amt. of distd. H_2O , reduce in a mortar to a homogeneous mass and add sufficient distd. H_2O to give 50 cc. vol. Add this milk of lime to a soln. of 83.63 g. pure, crystd. cacodylic acid in 100 cc. distd. H_2O , shake, close the receptacle and allow to stand for some time; 95.15 g. Ca cacodylate are thus obtained. Add this soln. to a soln. of 84.25 g. FeSO_4 (crystd. from alc.) in 100 cc. of a 10% aq. soln. of lactose (to prevent oxidation of Fe'' cacodylate), shake, allow to stand in a closed vessel for several days, then filter rapidly and complete the vol. of the filtrate to 300 cc. with a 10% soln. of lactose in distd. H_2O ; this final vol. should then contain 100 g. pure Fe'' cacodylate. Although this soln. contains a Fe'' salt, it does not possess a pronounced green color; such color is developed, however, if 10 g. citric acid be added before completing the vol. to 300 cc. A proportion of 30 cc. of the above soln. of Fe'' cacodylate, 20 g. tincture of nux vomica and sufficient 10% soln. of lactose in distd. H_2O to make 1000 g. corresponds to the original formula of Piccaluga; 10 g. of this prep. contain 0.10 g. Fe'' cacodylate and 0.20 g. tincture of nux vomica. B. proposes the following as an improved formula for this prep.: 30 cc. Fe'' cacodylate soln. (prepd. as above), 20 g. tincture of nux vomica, 500 g. 10% soln. of lactose in distd. H_2O , 100 g. 95% alc., 5 g. citric acid and sufficient neutral glycerol (31°) to make a final wt. of 1000 g.

H. S. PAINE.

Vetiver oil. ANON. *Bull. Imp. Inst.* 13, 308(1915).—Samples of roots of the vetiver plant (*Vetiveria zizanioides*) collected at different seasons in various parts of India gave yields of oil varying from 0.37 to 1.14% on steam distn. The quality of the oil depends mainly on the season at which the roots are collected; other factors such as soil and locality are of minor importance.

R. L. SIBLEY.

Incompatibility of urotropine with lithium benzoate and some official medicaments. ANON. *Bull. soc. pharm. Bordeaux; Schweiz Apoth. Ztg.* 53, 440-2(1915).—A dry mixt. of urotropine with BzOLi kept in paper begins to cake the first day, and is liquid the 3rd day. No chem. decompn. takes place; no NH_3 nor HCHO is given off. In moist air, a mixt. of 0.25 g. of each substance gains 0.35 g. in 2 days. Drying restores the original mixt. Urotropine itself is slightly hygroscopic. Mixed with Li_2CO_3 , or with

BzOH, or with BzONa, or BzONH₄, or Na salicylate, salol or salophene, the same liquefaction is produced. With Na₂CO₃ or NaHCO₃, chem. decompn. takes place in addition, NH₃ being liberated. With aspirin, AcOH is set free, soon followed by HCHO. With antipyrine (cf. C. A. 6, 2669) the odor of phenol appears and the mixt. liquefies.

S. WALDBOTT.

Bismuth preparations of the Codex. F. GOLDBY. *Pharm. J.* 94, 826-7(1915).—The following changes are suggested: In *mist. bismulhi comp.* and *mist. bismulhi comp. cum morphina*, substitute an equiv. amt. of carmine for the unsatisfactory liquor carmini, Brit. Pharm. Cod. In the prepn. of *mist. bismulhi comp. cum pepsino*, substitute sol. Bi tartrate in scales for Bi citrate and NH₃. Take Bi tartrate, 9.15; stronger glycerin of pepsin B. P. C., 12.50; soln. of strychnine B. P., 7.50; tinct. of cudbear B. P. C., 7.50; dil. HCN, 3.34; CHCl₃-H₂O (1 in 200), to make 100 parts. The Bi tartrate dissolves completely in about 63 parts of H₂O (shaking for 1 hr.), the finished mixt. is bright, needs no filtering, and seems permanent. The reaction is slightly acid, favorable to pepsin, and cudbear is preferable to carmine. The mixt. can be made readily in large or small quantities.

S. WALDBOTT.

History of the salicylic compounds and of salicin. GORDON SHARP. *Pharm. J.* 94, 857(1915).—The history, pharmacology and therapeutics of these compds. are recorded.

S. WALDBOTT.

Examination of pulvis rhei compositus (Gregory's powder). G. D. ELSDON and HERBERT HAWLEY. *Pharm. J.* 95, 100-1(1915).—The Brit. Pharm. 1914 gives the comp.: Light MgO 66, powdered rhubarb root 22, powdered ginger 12. A reasonable limit for H₂O is 4%; 15 com. samples contained 2.1 to 5%. The av. % of H₂O in MgCO₃, Brit. Pharm. (3 samples), was 0.5, rhubarb (10 samples) 9.5, ginger (10 samples) 10.5. Amt. of ash calcd. is 67.5%; 15 com. samples gave 57.1 to 72.5%. Alkalinity of ash (detd. with N HCl and Me orange) is about 4.5% less, due to CaO and non-alkalinity of ash in rhubarb and in ginger. The amt. of CO₂ (partly due to absorption) should not be more than 3%. More than 5% indicates adulteration with MgCO₃. Its amt. is detd. by the nitrometer method of Paul and Cownley, 1898, with E. and H.'s correction for absorption of CO₂ by 10 cc. 0.2 N HCl = 7.5 cc. (When 0.5 g. MgO are dissolved, the vol. is only 5.1 cc.) With 0.5 g. of powder, the corrected number of cc. of CO₂ obtained at 65° F. and 760 mm., times 0.364, gives % of CO₂. The combined amts. of rhubarb and ginger are detd. as the sum of cold H₂O ext., residue of 0.5 N AcOH ext. and 10% allowance for H₂O. The relative amts. of rhubarb and ginger may be calcd. from the detd. alcoholic or aq. exts. of the mixt., and the established corresponding values of each constituent. Ginger (30 samples) gave 13.3% H₂O ext., 5.8% alc. ext.; rhubarb (15 samples) 44.0-30.0% H₂O ext., 36.4-28.8% alc. ext. For 7.8% alc. ext. of the mixt., the calcd. ratio is 62:38. A table gives results of analyses of 21 samples, viz., H₂O, ash, alkalinity of ash as MgO; CO₂; cold H₂O ext.; amts. insol. in 0.5 N AcOH.

S. WALDBOTT.

Extraction by immiscible solvents. P. A. W. SELF. *Pharm. J.* 95, 164-5(1915).—A discussion of the adaptabilities of Et₂O, CHCl₃, petroleum ether, amyl alc., C₆H₆, CS₂ and CCl₄; also an account of the methods of preventing, and of sepg. emulsions. S. lays stress on the use of large vols. of solvent for the purpose of counteracting emulsions.

S. WALDBOTT.

A short history of the synthetic aniline alkaloidal derivatives, phenazone, phenacetin and acetanilide. GORDON SHARP. *Pharm. J.* 95, 197-8(1915).—An account of the pharmacology and therapeutic action of these compds. is included. S. W.

Merzalin, a substitute for vaseline. HESSELAND. *Pharm. Zentralk.* No. 19 (1915); VASTERLING. MANNICH AND KATHER, *Apoth. Ztg.* Nos. 45, 46(1915); *Schweiz. Apoth. Ztg.* 53, 353-4(1915).—For merzalin, white, V. finds I no. 1.56, sapon. no.

o, m. p. 43.5, H_2O , etc., 10.44%, ash 30.68%, of which 4.86% is sol. in HCl . Merzalin, yellow, I no. 9.0, sapon. no. 0, m. p. 40-42° (indistinct), H_2O and volatile hydrocarbons 12.4%, ash 43.91%, HCl -sol. 4.11%. M. and K. find 37% talcum, about 8% H_2O and 55% of mineral fats, i. e., a vaseline "stretched" with H_2O and talcum.

History of pharmacopeias. C. BUEHRER. *Schweiz. Apoth. Ztg.* 53, 354-6, 367-71, 381-5, 400-2 (1915).—Special reference is made to the development of the Swiss pharmacopeia.

S. WALDBOTT.

Essential oils. SCHIMMEL & Co. *Semi-Ann. Report* Oct., 1914-Apr., 1915, 114 pp.—*Ageratum oil*, distd. from *Ageratum conyzoides*, L., Annam, yield 0.0054%, d_{15} 1.1090, opt. rot. $-1^{\circ} 20'$, acid no. 0.9, ester no. 11.2, nearly all sol. in 5 + vols. of 80%, in 0.5 vol. of 90% EtOH. Two samples of *alant oil* partly deprived of alantolactone, were thick, dark brown and gave d_{15} 1.0407 and 1.0430, n_D^{20} 1.52324 and 1.52245, acid nos. 14.9 and 10.9, ester nos. 155.6 and 167.3, acetyl ester no. (of one oil) 181.6. Both oils gave clear soln. with 95% EtOH up to 1 vol. The yield of *ammoniacum oil* was 0.19%, d_{15} 0.8875, opt. rot. $+1^{\circ} 37'$, n_D^{20} 1.47250, acid no. 3.7, ester no. 40.5, acetyl ester no. 106.4. The oil was deep yellow, of peculiar, unpleasant odor, sol. in 0.5 + vol. 90% EtOH. *Cajuput oil* from Annam contained 40.5% cineole (resorcinol method), d_{15} 0.9198, opt. rot. $-2^{\circ} 36'$, sol. in 1.8 vols. of 70%, in 0.5 vols. of 80% EtOH. (*Bull. Roure-Bertrand Fils*, April, 1914.) *Calamus oil* from Japan recently shows neg. rotation, the other consts. are normal and the aroma is strong; d_{15} 0.9846 to 0.9863, opt. rot. $-5^{\circ} 36'$ to $-11^{\circ} 25'$, n_D^{20} 1.51655 (one detn.), acid no. 0.9 to 1.1, ester no. 1.3 to 9.1. Sol. in about 2 vols. of 80% EtOH and in 0.4 vols. or less of 90% EtOH. Com. *cananga oils* had been mixed with fatty oils as shown by high ester nos. (38.2-42.9), insolubility in 10 vols. of 95% EtOH and the characters of the products of distn. with steam. *Korarima cardamom oil*, yield 1.2%, gave d_{15} 0.9038, opt. rot. -3° , acid no. 3.6, ester no. 22.1, sol. in 0.5 vol. 90% EtOH. Its odor differs from that of regular cardamom oil. (E. M. Holmes, *Perfum. Essent. Oil Rec.* 5, 302 (1914).) To det. the amt. of rosin in *cassia oil*, dissolve 5 g. of oil in 20 cc. of 70% EtOH, add 10 cc. or more of $Pb(OAc)_2$ soln., wash ppt. with 70% EtOH and dry at 100° to const. wt. The amt. of rosin added in certain regions is believed to be 10%. (*Perfum. Essent. Oil Rec.* 5, 264 (1914).) *Copaiva balsam* from Manaos gave the consts. d_{15} 0.9280, opt. rot. $-29^{\circ} 30'$, n_D^{20} 1.50457, acid no. 23.2, ester no. 5.5. It yielded 81% of oil, d_{15} 0.9036, opt. rot. $-32^{\circ} 28'$, n_D^{20} 1.50092, acid no. 0.6, ester no. 6.4. Two more samples of Manaos balsam yielded 83.4 and 79.6% of oil, d_{15} 0.9068 and 0.9095, opt. rot. $-16^{\circ} 4'$ and $-30^{\circ} 6'$, n_D^{20} 1.50045 and 1.53012, acid nos. 0.3 in both, ester nos. 3.7 and 0.9. Both were sol. in 6+ vols. of 95% EtOH. *Cubeb oil*, distd. in England (6 samples) gave d_{15} 0.919-0.924, opt. rot. -27.2° to -29.4° , n_D^{25} 1.4928 to 1.4950. 14 to 32% distd. below 250°; 64 to 80% between 250 and 280°. One other sample showed d_{15} 0.927, and 50% distd. below 250°; 44% between 250 and 280°. (J. C. Umney and E. T. Brewis, *Perfum. Essent. Oil Rec.* 5, 256 (1914).) *Daniella thurifera*. Balsam received from W. Lenz (cf. C. A. 8, 2921) yielded by distn. with steam 58% of colorless oil, d_{15} 0.9216, opt. rot. $-5^{\circ} 43'$, n_D^{20} 1.50670, acid no. 0, ester no. 1.9, not clear soln. with 10 vols. 95% EtOH; b. p. 268°, with decompn.; 74% b. r. 95 to 108°. Cadinene was abundantly present. Artificial *bergamot oil*. Two samples gave d_{15} 1.0432 and 1.0858, opt. rot. $+7^{\circ} 30'$ and $+7^{\circ} 30'$, acid nos. 0.3 and 0.9, ester nos. 403.3 and 577.1. The bulk of the ester was not linalyl acetate, but phthalic ester in one case and glyceryl acetate in the other (about 70% of each). *Mandarine oil*, Japanese. Three samples received were colorless, showing that the oil was made by steam distn., not by pressure as in Italy. The odor was mainly that of limonene. The consts. of the 3 oils were, resp., d_{15} 0.8489, 0.8528, 0.8541; opt. rot. $+92^{\circ} 35'$, $+73^{\circ} 36'$, $+68^{\circ} 5'$; opt. rot. of the first 10% of distillate $+91^{\circ} 32'$, $+66^{\circ} 10'$, $+60^{\circ} 48'$,

acid nos. 0.3, 0.3, 0.3; ester nos. 3.7, 3.6, 4.6; sol. in 90% EtOH, 5.5+, 5.5+, 5+ vols. Three samples of *mikan oil* showed similar consts. d_{18} 0.8483, 0.8478, 0.849; opt. rot. +92° 20', +90° 56', +90° 35'; sol. in 6+, 6.2+ and 10 vols. of 90% EtOH. The limits for *Italian mandarin oil* are: d_{18} 0.854 to 0.859; opt. rot. +65 to +75°, opt. rot. of the first 10% of distillate little less or up to 2° higher than that of the original oil; acid no. up to 1.7, ester no. 5 to 11; more or less cloudy soln. with 7 to 10 vols. of 90% EtOH. *Oil of sweet orange* from Jamaica showed the following limits: d_{18} 0.8481 to 0.8491; opt. rot. (20°) +97° 43' to +98° 3'; opt. rot. of the first 10% of the distillate +96° 14' to +97° 30', always somewhat lower than the original oil; n_D^{20} 1.46984 (1 detn.) evapn. residue 1.4 to 2.0%. Detn. of aldehyde (calcd. for decylaldehyde) with PhNH.NH₂ 2.3, 2.7 and 3.8%. *Oil of bitter orange* from Jamaica: d_{18} 0.8517 to 0.8537; opt. rot. (20°) +92° 57' to +96° 58'; opt. rot. of the first 10% of distillate +92° 20' to +96° 40' (in 1 case higher than the original rotation); n_D^{20} 1.47171 (one detn.); evapn. residue, 2.6 to 3.2%; aldehyde, 0.75 and 1.5%. *Pine needle oil of Pinus heterophylla* gave the following consts.: d_{18} 1.48568, acid no. 0.6, ester no. 10.1, sol. in 7+ vols. of 90% EtOH with turbidity. About 70% of the oil distd. up to 72° (3 mm.). The distillate contained: *l*- α -pinene, *l*- β -pinene (probably also camphene). From the residue, NaHSO₃ extd. traces of an aldehyde having the odor of lauric aldehyde. It faintly appears in the odor of the oil. The oil of *Pinus palustris* gave d_{18} 0.8849, opt. rot. -30° 15', n_D^{20} 1.48277, acid no. 0.9, ester no. 4.6, sol. in 6 vols. 90% EtOH with slight opalescence. About 57% of the oil distd. up to 40° (6 mm.). The residue again gave with NaHSO₃ traces of a lauric aldehyde odor. The high-boiling portions, also of the oil of *P. heterophylla*, had the odor of sesquiterpene. The low-boiling fractions, b. 164-5° (d_{18} 0.8701; opt. rot. -17°) contained *l*- α -pinene and β -pinene. The oil of *Pinus ponderosa* did not react with NaHSO₃ soln. It had the consts. d_{18} 0.8796, opt. rot. -17° 16', n_D^{20} 1.48033, acid no. 0.6, ester no. 8.6, sol. in 5.5+ vols. of 90% EtOH. About 10% of the oil boiled between 159° and 164°, yielding small amts. of a nitrosochloride, m. 104°, indicating α -pinene. About 50% boiled from 164 to 170° (opt. rot. -18° 38') and contained *l*- β -pinene. From the fractions above 176° traces of an alc. having the odor of borneol were obtained. Com. *iris oil* differed markedly in the consts. for pure oil and in solubilities. It was adulterated with about 50% of castor oil. The oil obtained by distn. with steam did not conform to pure iris oil. The nature of the second adulterant was not detd. *Oil of Lavandula dentata* examd. by S. & Co. in 1905 and 1908 under the erroneous name of *Lavandula stoechas*, L., was yellowish brown and had a camphor-like odor, d_{18} 0.9620, opt. rot. +35° 30', n_D^{20} 1.47909, acid no. 5.16, ester no. 13.1, acetyl ester no. 67.9, sol. in 2+ vols. 70% EtOH, the dil. soln. is opalescent. The oil contained *d*-camphor (m. p. 175-175.5°, oxime m. 117-118°, semicarbazone m. 231°) and *d*-fenchone (oxime m. 165°), possibly also fenchyl alc. *Lavender oil* obtained by distn. with dry steam is said to become more sol. in 70% EtOH with time (*Perfum. Essent. Oil Rec.* 5, 147(1914).) This is doubted by S. & Co. *Lemongrass oil*, from Madras Presidency, has recently become poorly sol. in 70% EtOH, possibly due to the use of another grass species. Oil from Madras *white stalk* grass was yellow, resembling citronella oil in odor, etc., d_{18} 0.909, opt. rot. -10° 50', aldehyde (NaHSO₃ method) 9%, sol. in 0.8 + vol. of 80% EtOH, slightly turbid at 4 vols., insol. in 70%. Oil from *red stalk* grass was reddish brown and had the typical lemongrass odor, d_{18} 0.925, aldehyde (NaHSO₃ method) 71.5%, with 5 vols. 70% EtOH no clear soln., with 0.8 + vol. of 80% a clear soln. clouding with 5 vols. Upon steam distn., 78.7% of the oil passed, containing 81% aldehydes, and giving a clear soln. with 2.4 + vols. 70% EtOH. The residue was a reddish brown, viscid oil. The botanical origin of either grass is undetd. (*Bull. Imp. Inst.* 12, 222(1914).) Annam lemongrass oil, so-called "West Indian" oil, gave d_{18} 0.8846, opt. rot. -0° 4', sol. in 0.25 vol. 80%, milky with more EtOH. Citral

75%. Oil from Mayotta gave d_{15} 0.8917, opt. rot. $-0^{\circ} 22'$, sol. in 0.4 vol. 80% EtOH, strongly turbid with 2+ vols. Aldehydes 87%. (Bull. Roure-Bertrand Fils, Apr., 1914.) The low-boiling portions of oil of mastic (156° to about 170° , d_{15} 0.8599, opt. rot. $+32^{\circ} 57'$) contains chiefly *d*- α -pinene, with very little *dl*- α -pinene, and another terpene not as yet recognized. The solid fatty acid contained in *musk-seed oil* proved to be palmitic acid. The yield of *clove oil* from Mauritius cloves (cf. C. A. 8, 2598) was 10.2 and 11.5%; from the leaves, 1.62%. *Palmarosa oil* from Java is of good quality, d_{15} 0.8906 to 0.8920, opt. rot. $+0^{\circ} 30'$ to $+0^{\circ} 42'$, acid no. 1.2 to 1.8, ester no. 37.5 to 51.6, acetyl ester no. 272.7 to 276.8, corresponding to 94.3 to 96.0% total geraniol; sol. in 3 to 3.5+ of 60% EtOH; the dil. soln. was in some cases faintly opalescent. *Grains of paradise oil*, yield 0.5%, light brown and of a characteristic odor, d_{15} 0.8970, opt. rot. $-3^{\circ} 10'$, n_D^{20} 1.49116, acid no. 2.7, ester no. 41.2, acetyl ester no. 63.9. It is insol. in 90% EtOH, miscible with less than 1 vol. of 95% EtOH to a clear liquid. *Oil of Roman Chamomile* was distd. from double flowers (official) with a yield of 1.75%, d_{15} 0.9097, opt. rot. $+1^{\circ} 10'$, n_D^{20} 1.44418, acid no. 11.2, ester no. 277.2, sol. in about 6 vols. of 70% EtOH with sepn. of much paraffin. Opt. rotation may reach $+3^{\circ}$, but S. & Co. repeatedly obtained distillates also with faint neg. rotation, e. g., $-2^{\circ} 30'$, detected by the aid of E. Beckmann's lamp (C. A. 7, 1639). *Rose oil*, Russian, from Tiflis, gave d_{15} 0.8618, opt. rot. $-2^{\circ} 28'$, congealing p. $+19^{\circ}$; stearoptene, 23%; free acid calcd. as AcOH, 0.37%; ester calcd. as rhodinyl acetate, 2.79%; rhodinol (citronellol), 27.53%; geraniol and β -Ph Et alc. 41.44% terpenes, 4.77%. (Cf. C. A. 9, 352.) *Oil of turpentine* from *Pinus Jeffreyi* gave d_{15} 0.7051, opt. rot. $-0^{\circ} 10'$, n_D^{20} 1.39653, acid no. 0, ester no. 5.2, acetyl ester no. 8.7, sol. in 5.5 vols. of 90% EtOH. The balsam yielded 9.4% of oil. Most of the oil distd. between 96 and 100° , consisting chiefly of *N*-heptane (A. W. Schorger, C. A. 8, 1513). The aldehyde contained in the higher fractions is not citronellal (Schorger) but *N*-decylaldehyde (d_{15} 0.8212, opt. rot. $\approx 0^{\circ}$). Its *thiosemicarbazone* m. 99° to 100° , that of *N*-nonylaldehyde m. 77° , of *N*-octylaldehyde m. 94 to 95° , of citronellal m. 54 to 55° . Linalool and Me-chavicol were also present. *Oil of vetiver* from the Fiji islands, received from the Imperial Inst. (London), gave d_{15} 1.0164, n_D^{20} 1.52058, acid no. 31.1, ester no. 17.3, acetyl ester no. 143.7, sol. in 1 vol. 80% EtOH, turbid with 2+ vols. The constns. of oil from East Indian root detd. by the Imp. Inst. are d_{15} 1.0052, opt. rot. $+15^{\circ} 25'$, n_D^{20} 1.51880, acid no. 29.6, ester no. 12.5, acetyl ester no. 141.2, sol. in 1.5+ vols. of 80% EtOH. For oil from the Seychelles, S. & Co. detd. d_{15} 0.9863 to 0.9977, opt. rot. $+10^{\circ} 30'$ to $+19^{\circ} 25'$, n_D^{20} 1.52253, acid no. 8.2 to 16.3, ester no. 10.7 to 17.2, acetyl ester no. 103.3 to 130.5. Two samples were sol. only in 90% EtOH (0.5+ vol.), 3 gave clear soln. with 1.5 vols. 80% EtOH, clouding with 3+ vols. *Ylang-ylang oil*: Of two samples from the Seychelles, the constns. of the first point to a cananga oil, of the second, to a true ylang-ylang oil, d_{15} 0.9200, 0.9567; opt. rot. (21°) -30° , (20°) $-28^{\circ} 5'$; acid nos. 4.2, 3.3; ester nos. 42.2, 126.0; acetyl ester no. (for second) 181; sol. in 1 vol., in 0.8 vol. of 90% EtOH, then turbidity. The odor of the second oil is somewhat pungent, and far inferior to that of a good Manila distillate. The constns. of the first oil 3 yrs. later, were d_{15} 0.9250, opt. rot. (24°) $-28^{\circ} 36'$, acid no. 2.6, ester no. 53.5, sol. in $1\frac{1}{2}$ vol. 90% EtOH, then cloudy. A Mauritius oil gave d_{15} 0.9883, opt. rot. (20°) -30° , acid no. 7, ester no. 173, acetyl ester no. 211, sol. in 0.1 to 2.5 vols. 90% EtOH, then cloudy. (Bull. Imp. Inst. 12, 230 (1914).) *Copahillo oil*, probably from the Mexican wood of *Exothea copahillo* Radlk., gave d_{15} 0.8304, opt. rot. $+0^{\circ} 50'$, acid no. 10.2, ester no. 13.1, sol. in 0.5+ vol. 90% EtOH, contains at best small amts. of linalool. *Oil of the herb "Dox"* from Bombay, derived from a var. of *Artemisia maritima*, is a dark green oil of peculiar odor, yield 0.24%, d_{15} 0.9696, acid no. 1.8, ester no. 4.2, sol. in about 3 vols. 70% EtOH, sepg. paraffin. *Oils of false camphor tree*, *Hernandia peltata* Meissn. were distd. from the trunk wood

(I), the wood of the root (II), the whole fruits (III), the seeds (IV). Yields were 1.03-2.06% (I), 0.5% (II), 0.5% (III), 1.38% (IV); d_{15} 0.958 to 0.963 (I), 0.9667 (II), 0.9528 (III), 1.0044 (IV); opt. rot. $+83^{\circ} 45'$ to $+104^{\circ} 12'$ (I), $+126^{\circ} 15'$ (II), $+50^{\circ} 16'$ (III), $+87^{\circ}$ (IV); n_D^{20} 1.49695 to 1.50111 (I), 1.50383 (II), 1.49554 (III), 1.50614 (IV); acid no. 4.4 (I), 7.3 (IV); ester no. 47.1 (I), 110.4 (IV); % of aldehydes, detd. by means of Na_2SO_3 , 75-80 (I), 92.5 (II), 49 (III); solubility in EtOH, 2.5 to 4+ vols. of 70% (I), 2.5+ of 70% (II), 0.3+ vol. of 90%, more than 10+ vols. of 80% (III), more than 10 vols. of 70%, 0.5 vol. of 80% with opalescence (IV). All these oils except (III) had the characteristic odor of perilla aldehyde. *Himalaya cedar oil* from *Cedrus deodara* (Roxb.) Loud., is light brown, of balsamic odor, d_{15} 0.9530, opt. rot. $53^{\circ} 8'$, n_D^{20} 1.51565, acid no. 2.9, ester no. 14.9, acetyl ester no. 39.2, not entirely sol. in 10 vols. of 90%, miscible with 95% EtOH. The bulk of the oil is a sesquiterpene, not identified. It gave no positive test for cadinenene. *Oil of Libocedrus decurrens*, California; the odor recalls that of savin oil, d_{15} 0.8756, opt. rot. $-0^{\circ} 51'$, n_D^{20} 1.47544, acid no. 0.9, ester no. 4.6, sol. in 7+ vols. 90% EtOH, turbid. 22% of the oil boiled between 158° and 160° , containing *l*- α -pinene. *Oil of Melaleuca hypericifolia* from German East Africa, d_{15} 0.9145, opt. rot. $-0^{\circ} 18'$, n_D^{20} 1.46271, sol. in 2.5+ vols. 70% EtOH, eucalyptol content 72%. The const. of the oils from a broad-leaved (I) and a narrow-leaved (II) var. of *Melaleuca leucadendron* (Ger. E. Africa) are d_{15} 1.0019, 0.9056; opt. rot. $-3^{\circ} 44'$, $-0^{\circ} 22'$, n_D^{20} 1.52500, 1.47936; acid nos. 0.4, 0.7; ester nos. 7.6, 11.8; acetyl ester nos. 15.2, 84.8; sol. in 0.6+, 1.5+ vols. of 80% EtOH. Both oils differ essentially from cajuput oil (III) and from each other. Eucalyptol essential in (III) is absent in (I), and present in (II) only in small amt. 78% of the oil (I) is Me eugenol which is not found in (III). *Mother clove oil*, yield 2.03%, d_{15} 1.0933, opt. rot. $-3^{\circ} 11'$, n_D^{20} 1.54332, sol. in 1.8+ vols. of 70% EtOH; phenols (detd. with 3% NaOH), 88% (d_{15} 1.1210), 60% of which is eugenol, 40% a solid phenol insol. in H_2O , sol. in alk. and organic solvents, cryst. from EtOH, m. p. 44 to 45.5° ; b_{714} 309° to 310° , b_4 $146-9^{\circ}$, opt. rot. $=0^{\circ}$, d_{15} 1.188, Bz compd. m. 87 to 88° . *Oil of yama-nikkei bark* (wild cinnamon bark), gave d_{15} 0.9245 opt. rot. $+8^{\circ} 34'$, n_D^{20} 1.47779, acid no. 0.6, ester no. 14.8, sol. in 1+ vol. 80% EtOH; yield, 1.77 to 2.1%. The oil has a strong odor of camphor with faint odor of ginger. The fraction b_4 $40-75^{\circ}$ has the odor of terpenes and cymol. From the bulk of the oil b_4 $75-95^{\circ}$, camphor seps. in large amt. *Hardwickia balsam* received from Imperial Inst. (London) was viscid, reddish brown, greenish in thin layer, of faint, unpleasant odor. d_{15} 1.0222, acid no. 104.0, ester no. 32.6. Distn. with steam sepd. about 35% of colorless oil of faint odor, d_{15} 0.9080, opt. rot. $-6^{\circ} 7'$, n_D^{20} 1.50026, acid no. 0.3, ester no. 3.9, sol. in 5.5 + 95% EtOH, very slight opalescence. The residual resin was brittle, acid no. 160.6. *Vanillin*: A com. specimen from Italy contained only 18% of vanillin; the remainder was salicylic acid.

S. WALDBOTT.

Composition of Spiritus aetheris nitrosi (MARSHALL) 11H.

U. S., 1,149,582, Aug. 10. J. HUISMANN. Dehydrothiitoluidinedisulfonic acid of the formula

yellow leaflets, sol. in H_2O with a yellow color, forming a Na salt easily sol. in H_2O and an easily sol. yellow diazo compd., is made by heating the monosulfonic acid with $\text{H}_2\text{SO}_4 + \text{H}_2\text{O}$ for several hrs. to drive off all the H_2O .

U. S., 1,150,579, Aug. 17. C. COUTELLE and A. MORR. Copper salts of polymethylenebisimino acids, such as β -methyltetramethylenebisiminoacetic acid or tetramethylenebisiminoacetic acid, cryst. compds. sol. in H_2O and difficultly sol. in organic solvents, therapeutic agents for the treatment of tuberculosis, are formed by boiling the acid with H_2O and $CuCO_3$.

U. S., 1,150,580, Aug. 17. A. B. DAVIS. Alcamine ester of the formula

a local anesthetic, is produced by treating chloromethyl ω -bromopropyl ketone with EtMg bromide, condensing the tertiary alc. thus formed with dimethylamine to form dimethylaminomethylethylamylcarbinol and esterifying with BzCl . It forms white crystals.

U. S., 1,150,654, Aug. 17. R. BERENDES. Gallocoxylic acid compound containing iodine and bismuth; a red-brown powder, containing about 20% I and 45% Bi, insol. in H_2O and difficultly sol. in alc., ether, C_6H_6 and ligroin; split by dil. HCl with production of gallocoxylic acid; made by heating gallocoxylic acid and Bi oxydide together in H_2O at 100° . The compd. is an antiseptic and astringent. Cf. C. A. 8, 2220.

Brit., 8,917, Apr. 8, 1914. AKT.-GES. FÜR ANILIN FABRIKATION. Ureide of aminoanthraquinones, and aminoanthraquinones themselves, are prepared by heating ureide of 3-aminobenzoyl- α -benzoic acids with H_2SO_4 . Substituted acids containing Br, Cl, or I, or methoxymethyl, and sulfonic groups may be used. Ureide of 3-aminobenzoyl- α -benzoic acids, containing or not substituents such as Br, or Cl, and Me, methoxy, or sulfonic groups, are prepared by treating the alkali salts of the acids with COCl_2 in the presence of chalk, soda, etc. 3-Nitro- and -amino-4-sulfo-benzoylbenzoic acids are successively obtained by treating 3-nitro-4-chlorobenzoylbenzoic acid with Na_2SO_3 , and subsequently reducing the product. 4-Methyl-2'-benzoyl-3',4',5',6'-tetrachlorobenzoic acid and its 3-nitro and 3-amino derivs. are successively obtained by condensing tetrachlorophthalic anhydride with toluene, and then nitrating and finally reducing the nitro product. 3-Nitro- and -amino-4-methoxybenzoylbenzoic acids are successively obtained by treating 3-nitro-4-chlorobenzoylbenzoic acid with MeOH -potash lye, and subsequently reducing the product.

Brit., 9,237, Apr. 14, 1914. GES. FÜR ELEKTRO-OSMOSE. In mfg. a solution of silicic acid of low molecular weight, an alkali silicate soln. of 5-10% strength is placed in an anode compartment, the electrodes being preferably perforated and placed close to the diaphragm. To prevent passage of silica, in consequence of the presence of traces of foreign acids, the diaphragm is made of a material giving practically a zero potential, for instance a mixt. of carborundum and corundum, the process of 2,626, 1911 (C. A. 6, 1883), being employed. When the product is to be used medically, the anode is of Pt netting; otherwise it may be of Pb-Sb alloy. Brass wire netting may serve as cathode. The elec. pressure, initially low may be raised to 60-70 v. to remove the last of the alkali. Traces of foreign acids are then sepd. by transferring the silicic acid to a vessel serving as cathode and containing an anode surrounded by a diaphragm which may be of parchment paper; the elec. pressure may be gradually increased during this treatment. Reference is made to the prepn. of sol. silicic acid by decomposing SiS_2 or the methyl or other ester of silicic acid by prolonged b., and by the action of H_2O on SiCl_4 .

Brit., 9,261, Apr. 14, 1914. *GES. FÜR ELEKTRO-OSMOSE*. Stable metal sols are obtained by the use of sol. silicic acid; the pure silicic acid described in 9,237, 1914 (*supra*), is suitable. The process may be carried out by reducing the metal salt, *e. g.*, a Au or Ag salt, by a suitable reducing agent, such as hydrazine hydrate, in presence of the silicic acid soln. The prepn. may be purified electro-osmotically from electrolytes.

Brit., 9,472, Apr. 16, 1914. *BAYER & Co.* Ureas are prepared by treating with COCl_2 the compds. obtained by condensing nitrobenzoyl halides or their substituted derivs. with 1,8-aminonaphtholsulfonic acids and subsequent reduction of the nitro group. By repetition of the condensation and reduction processes, acids containing several aminobenzoyl residues may be obtained, and then converted into ureas. The ureas have a destructive action on blood parasites such as trypanosomes, and also have an affinity for cotton fiber. Azo dyes result by the combination of the above-described ureas with diazobenzene and other diazo compds.

18. ACIDS, ALKALIES, SALTS AND SUNDRIES.

T. LYNTON BRIGGS.

Purification of commercial hydrochloric acid. A. COIGNARD. *Ann. chim. anal.* 20, 145-6(1915).—Simple distn., rejecting about the first third of the distillate to remove all As, yields a very weak acid and is therefore too expensive on account of loss. Houzeau's process based on the addition of KClO_3 to convert As to AsCl_3 and then distg., collecting distillate from the start, yields a product free from Fe (best to add 2 to 3 cc. of H_3PO_4 to retort), H_2SO_4 or residue. However, it is very difficult to remove all Cl. All of the As is supposed to remain in the retort; but AsCl_3 is stable in HCl soln. only when cold, being slowly decomposed by conc. HCl on heating with the formation of AsCl_5 and Cl. FeCl_3 favors this reaction. The total distillate therefore contains As. By collecting the first products of distn. it is possible to eliminate the As, but the loss is considerable and the purity of the product uncertain. Bettendorf adds SnCl_4 to acid of over 16° Bé. to ppt. the As, lets stand 24 hrs., removes excess of SnCl_4 with HgCl_2 , decants from the ppt., filters if necessary, and distils till just pasty (if H_2SO_4 is present, add 3 to 4 g. NaCl before distg.). The product is free from As or other impurities. With acid of an initial concn. of 20 – 22° Bé. and the complete removal of the ppt. before distn., there is no danger of any As or SnCl_4 passing into the distillate. Duflos' process requires less care and yields a high grade product. Dil. the crude HCl to 17° Bé., add a pinch of MnO_2 or KClO_4 if SO_2 is present; add a few pieces of cleaned com. Cu foil and let stand 24 hrs. at about 30° . Remove and clean the foil, return to the acid and let stand 24 hrs. All As is pptd., free Cl removed, FeCl_3 converted to FeCl_2 . Decant and distil in the presence of Cu shavings. Distn. may be carried quite far, as in the preceding. Methods based on the use of 4 to 6 g. of $\text{K}_2\text{S}_2\text{O}_8$ per l., H_2S or BaS to remove As before distn. are not as good as the preceding. In the processes of Houzeau and Duflos any Sb remains in the retort; in that of Bettendorf traces of Sb may be entrained with the impure acid. F. W. SMITHER.

Method of transferring acid without waste. ANON. *Elec. World* 66, 367(1915).—The app. consists of a bronze centrifugal pump and flexible tubes connected with inlet and outlet. A short suction hose is inserted in the container while a long hose conveys the acid to the battery jars. Corrosion is minimized by forcing NH_3 and H_2O through the pump after each use. W. H. BOYNTON.

The feasibility of continuous causticizing. R. W. S. *Met. Chem. Eng.* 13, 514-5 (1915).—A discussion of the feasibility of adapting continuous agitation and contin-

uous countercurrent washing to causticizing soda ash by means of CaO, according to the equation $\text{Na}_2\text{CO}_3 + \text{CaO} + \text{H}_2\text{O} = 2\text{NaOH} + 3\text{CaCO}_3$. According to the flow sheet of the proposed process CaO and Na_2CO_3 sufficient for 24-hrs. operation are to be reduced to $\frac{1}{4}$ in. and smaller and stored in the hoppers, from which the CaO and Na_2CO_3 would be fed continuously and in the desired proportion to the first Dorr agitator of the series. Weak soln. from the washing system would be transferred directly to this agitator. A series of agitators is advisable, the size of the agitators being a function of the time required to reach chem. equil. The heat necessary to maintain the desired temp. would be supplied by steam coils in each agitator. The mixt. would gravitate between the agitators and finally to the first of the series of Dorr thickeners; overflowing from this thickener would be the clear NaOH soln. for storage and use. The CaO mud as it settles out would be discharged and transferred to the succeeding thickener by means of a pump, being thoroughly mixed with the wash liquor flowing from the third thickener in the feed launder before entering the tank. The overflow from the second thickener would be transferred to the first agitator and the CaO mud discharged and transferred to the third thickener. Wash H_2O would be introduced into the feed launder of the last thickener and mixed thoroughly with the CaO mud which would be discharged from this last machine with a very low NaOH content. The "mud" from the last thickener could be fed to a continuous dewatering filter and thence to calciners and the CaO so obtained returned to the causticizing system. *Advantages:* the personal element would be reduced to a minimum. The reaction would proceed under the most favorable conditions for the production of a soln. of a given strength, thus insuring the highest possible yield of NaOH and the washing would be accomplished with the least possible H_2O . A relatively large amount of NaOH soln. of uniform strength would be made in a very compact plant (a space of 40 ft. sq.). Power consumption would be very small (10 h. p. delivered to a line shaft). Labor required would consist of filling the feeding hoppers. The principles set forth are the same that have largely taken the place of intermittent decantation and filtration methods in the treatment of metalliferous ores.

Brit., 9,370, Apr. 15, 1914. J. S. CAMPBELL. A plastic composition of comminuted leather, animal fat, fatty oil, or resin oil, or a combination of these, together with powdered filling-material, such as $MgCO_3$, lime, and French chalk, and a resilient vulcanizable binder, with or without alkali or fibrous material, is used for making leather and rubber substitutes and waterproof and elec. insulating materials. The compn. may be combined with a vulcanizing agent, such as S, with or without tannic acid and bark ext., and subsequently vulcanized; or it may be softened or rendered fluid by means of a solvent, and applied to a canvas or other backing, with or without subsequent vulcanization. The materials may be boiled together and partly or completely dried before vulcanization, and the resilient vulcanizable binder, which may be in soln., may consist of Jelutong, rubber, gutta, balata, rubber waste, etc. $K_2Cr_2O_7$, borax, and metal dust may also be added. The calendered sheets may be wound upon a drum and immersed in a tank containing a soln. of alum and boric or tannic acid or bark ext., the tank being heated in a vulcanizing pan to a suitable temp. The product may be used for tires and tire covers, washers, jointing, boot soles, machine belting, etc.

Brit., 9,384, Apr. 15, 1914. GENTHNER CARTONPAPIERFABRIK GES. Mfg. metal or color foil from a compn. metal or color powder or metal leaf, by using a backing of thin paper or other fibrous material which serves as a support for the foil during its prepn., but is afterwards destroyed or "broken down," leaving the foil ready for use. A backing of thin paper satd. with a 10% of soln. of H_2SO_4 is coated with an adhesive and sprinkled with metal or color powder, or a mixt. of adhesive and metal or color powder, or with leaves of metal. The coated paper is then passed over heated plates or rollers to destroy or break down the fiber of the paper, leaving the foil ready for use. The residual acid may be neutralized before the strip is coated, or the strip may be treated with acid after coating.

Ital., 135,019, Sept. 4, 1913. P. CANTILENA. Mfg. sulfur di- and tri-oxides by igniting a mixt. of plaster of paris and clay (in the form of a paste), with the employment of portland cement. Common chalk may be used instead of plaster of paris.

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

A chemical study of colored glasses of the middle ages. G. CHESNEAU. *Compt. rend.* 160, 622-4(1915).—C. reports analyses of violet, blue, green and red glasses

from the cathedral at Rheims: The results show that the 4 glasses have a common character and apparently the same origin. The powdered glasses are completely attacked by hot conc. acids, although they have resisted atm. agencies; after grinding away the lustrous outer layer, polishing with CaCO_3 reproduces the brilliant, lustrous finish. Impure pyrolusite was used as the coloring agent for the violet glass, the impurities (Fe, Cu, Co) giving the flesh tone that cannot be obtained with pure Mn oxide. For the blue glass apparently CuO was added to the zaffer obtained from cobaltite. The absence of Ni and the high Mn content indicate that the glass workers of the 13th century were familiar with the properties, uses, etc., of these elements. The tint of the green glass was obtained by a mixt. of CuO and Fe_2O_3 , the shade being influenced by a little Co and much Mn. The color of the red glass is due to an extremely thin enamel containing Cu_2O ; after removing this enamel, the glass is a clear green color, like ordinary bottle glass. The high K_2O content of the violet and green glasses was necessary to obtain the violet of Mn and the green of Cu, operating in a very oxidizing atm. (adding KNO_3 to the ordinary glass composition to avoid the reducing action of the furnace gases).

F. W. SMITHER.

Report of the British Science Guild with reference to the manufacture of optical instruments and matters relating thereto. *Chem. News* 111, 178-80(1915).—Chance Bros. have quadrupled their plant since the outbreak of the war and the supply for England of optical glass for telescopes, binoculars, range finders and other service instruments is sufficient. For photographic lenses the glass supply is quite inadequate; one reason is the scarcity of pure Ba compds. A wide range of optical glasses is not obtainable in England. Chance Bros. list 20 to 30 types while Schott lists 70. Ba glasses of high index and low dispersion are especially needed. The greatest difficulty is to find a refractory lining (for the clay pot) that will withstand the solvent action of the molten glass.

J. B. PATCH.

The properties of kaolin and its behavior toward dyestuffs, caustic alkalies and alkali silicates. P. ROHLAND. *Glasind.* 26, Nos. 19-20-21-22(1915).—R. has tested the adsorptive power of clays with methyl orange, indigo and other dyestuffs. The amt. of adsorption is proportional to the amt. of colloidal matter present. He finds kaolin to be slightly superior in this respect to English china clay and hence more plastic. The acidity of the dyestuff is a factor. Methyl orange, for instance, in acid solns. is much more easily adsorbed by the clay than in alk. soln. Hence it is assumed that the acid soln. favors the formation of colloids and the alk., of crystalloids. Undissociated colloidal alkali silicates ppt. the quartz and sand grains in kaolin and hydroxyl ions coagulate the kaolin particles.

J. B. PATCH.

U. S., 1,150,467, Aug. 17. J. WEBER. Opaquing composition for use in vitreous enamels is formed by hydrated stannic oxide containing about 10% H_2O and 3-5% of alkali.

U. S., 1,150,772, Aug. 17. I. KREIDL. An opaquing material for white enamels is made from an alk. compd. of Zr or other opaquing metal by treating with a weak

acid and washing to remove part of the combined alkali and improve the opaquing effect of the material. Cf. *C. A.* 9, 701.

Brit., 8,892, Apr. 8, 1914. W. J. GEE. Drying china-clay, clay, fullers earth pigments, whitening, etc., with the aid of intense heat while the material is kept in motion by an endless permeable band to which it is supplied in thin films. Waste heat from the drier may be used to preheat the material. The permeable band may consist of a series of parallel wires.

20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

Further results in investigating properties of high magnesia portland cements. P. H. BATES. U. S. Bur. of Standards. *Concrete-Cement Age* 7, C. M. S. 1-7(1915); cf. *C. A.* 8, 1653.—Further chem., petrographic and physical test data are given. Monticellite ($\text{CaO} \cdot \text{MgO} \cdot \text{SiO}_2$) is first noted in burn containing 8.03% MgO. Spinel is also observed in high MgO clinker. High MgO cements produced concrete showing as good a deportment as regards expansion as the low MgO cements. Satisfactory 13 and 26 week strength results are obtained with a cement containing 10.33% MgO. In a cement containing 18.98% MgO whose neat tensile specimens disintegrated before the end of 1 yr., cracks are noted filled with crystals of sulfo-aluminate of lime, brucite [$\text{Mg}(\text{OH})_2$] and $\text{Ca}(\text{OH})_2$.

A. A. KLEIN.

Oil-mixed portland cement concrete. Office of Public Roads. U. S. Dept. of Agr., *Bull.* No. 230(1915).—Admixtures of certain mineral oils in proportions not to exceed 10% of cement used do not lessen the tensile strength of mortars. The decrease in compressive strength of mortar and concrete is not serious. Concrete mixed with oil takes perhaps twice as long to set, but the increase in strength is nearly as rapid in the oil-mixed materials as in plain concrete. The former is not impervious to heavy water pressure but practically so under low heads. The oil should be a fluid petroleum product containing no fatty or vegetable oils. It shall have a d. not greater than 0.945 at 25° and a flash pt. of not less than 150° by the closed-cup method. When 1 part of oil is shaken with 2 parts of 0.01 *N* NaOH there should be no emulsification. To damp-proof an old surface a mortar of 1 part cement, 2 parts sand and containing 5% of oil should be sufficiently non-absorbent. Sand and cement should be first mixed with the proper amt. of H_2O into a stiff mortar, to which is added the correct amt. of oil, and the whole mass is again thoroughly mixed until all the traces of oil have disappeared. Extreme care must be exercised in proportioning, mixing and placing the concrete.

A. A. KLEIN.

Broken concrete as aggregate for paving. ANON. *Eng. Record* 71, 816(1915).—Old concrete broken up into $\frac{1}{4}$ to $2\frac{1}{2}$ " sizes was used as aggregate for paving at Kansas City. 28 day tests on 1:3:6 concrete showed an av. crushing strength of 1260 lbs. per sq. in.

A. A. KLEIN.

Specification for wood paving block oil. H. M. NEWTON, S. R. CHURCH AND H. VON SCHRENK. *Wood-Preserving* 2, 44(1915).—The following specification has been adopted by the Comm. on Standard Specifications of the Creosoted Wood Paving Block Bureau: (1) The sp. gr. shall not be less than 1.07 nor more than 1.11 at 38°. (2) Not more than $2\frac{1}{2}\%$ shall be insol. by continuous hot extn. with C_6H_6 and CHCl_3 . (3) On distn., which shall be made exactly as described in the rept. of the Committee D-7 of the Am. Soc. for Testing Materials, 1915, the distillate based on water-free oil shall be within the following limits: Up to 210°, not more than 5%; up to 235°, not more than 30%; up to 315°, at least 50%; up to 355°, at least 70%. (4) The sp. gr. of the distillate between 235° and 315° shall be not less than 1.03 at 38° com-

pared with water at 15.5°. (5) (a) The sp. gr. of the residue above 355° shall be at least 1.23 at 25° compared with water at 15.5°. (b) If the residue does not conform to requirements 5 (a), it shall be of a cryst. or granular nature and non-ductile, and it shall have a sp. gr. of not less than 1.14 at 25° compared with water at 15.5°. (If the residue falls within requirements 5 (b), the whole oil may have a sp. gr. of not less than 1.05 at 38° instead of 1.07 as required in (1).) (6) The sp. viscosity at 82° shall not exceed 1.2. The term "sp. viscosity" shall mean the number of secs. found for the sample tested divided by the number of secs. for water at 20° given in the official certificate for the viscosimeter used. (7) The oil shall not contain more than 3% of water. This specification was drawn up definitely to limit the proportions of tar that may be added to the distillate of creosote oil.

E. J. C.

U. S., 1,150,295, Aug. 17. S. B. NEWBERRY. Recovering alkalies from the stack-gases of cement kilns. Flue-dust is sepd. from the gases, which are then cooled by passing over H₂O-cooled tubes, washed with H₂O and freed from liquid by passing through coke. Insol. material is removed from the soln. of alkali metal salts obtained and this together with the flue dust is returned to the kiln. Part of the soln. is evapd. and the remainder is used for further washing the gases. Cf. C. A. 9, 364.

U. S., 1,150,481, Aug. 17. J. H. AMES. Bituminous paving composition; made by mixing dry powdered CaO with earth, sand or gravel, slaking the CaO and while the mixt. is hot from the reaction adding 4 times the wt. of CaO of hot liquid bituminous or pitchy material, then adding more CaO and thin alk. cement mortar.

U. S., 1,150,499, Aug. 17. J. W. CARR. Wood-preserving composition composed of equal amts. of pine tar, linseed oil, rosin oil and kerosene.

Brit., 8,645, Apr. 6, 1914. A. ANKER. In a process and app. for slaking lime or other mortar material, the material is fed into an inner chamber having perforations and surrounded by an outer chamber revoluble about an axis. The material is fed in by an opening having a suitable closing-device, and steam is supplied to the outer chamber through one of the trunnions. After a time, the condensed H₂O is withdrawn and the app. is rotated. The material is discharged by the charging opening. Cf. C. A. 8, 2793.

Brit., 9,281, Apr. 14, 1914. M. A. POPKESS. App. for heating, drying, and pulverizing earthy substances, such as soil, loam, clay, or peat, for the purpose of making paving-material, consisting in providing an external drum having internal rotary means for raising the material to an internally heated and rapidly rotating pulverizing drum, the fine dust being sepd. out as fast as it is formed by means of a screen arranged between the 2 drums.

21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

Fuel and motor-fuel in war times. AUFHAUSER. Hamburg. *Chem. Ztg.* 39, 545-7(1915).—A general review of conditions in Germany.

J. H. MOORE.

Sampling in colliery work. T. W. D. GREGORY. *Iron Coal Trades Rev.* 90, 779 (1915); *Colliery Guardian* 109, 1168-9(1915).—In sampling by the coning and quartering method 2 distinct processes are entailed: (1) reducing the bulk of sample and (2) re-

ducing the size of particles of material. G. quotes results of expts. that show that to keep the error below 1%, with the max. size of particle 2 in., the amt. of sample should be 8,300 lbs.; with 4-mesh 1,100 lbs., 8-mesh 120 lbs., 20-mesh 3 lbs. Slack should be sampled at the screens; if in wagons it should be holed from top to floor in at least 3 places taking a center line down the length of the wagon. In sampling a face remove dust and fragments for a width of 4-5 ft. from roof to floor. In the middle of this remove the coal to a depth of $\frac{3}{4}$ in. and 9 in. wide. Take the sample by means of a pick cutting in the prepared surface, keeping 5-6 lbs. per foot of seam. Notes on sampling mine air and water are appended.

H. L. OLIN.

Coal. G. DE P. COTTER. *Rec. Geol. Surv. India* 44, 163; *Bull. Imp. Inst.* 13, 322(1915).—Analysis of 22 samples of coal found in Upper Burma and the region near the Yaw River showed comps. as follows: fixed C 29-39, volatile matter 32-37, moisture 15.6-21.6, ash 7.3-21.7% and calorific value from 4500 to 4835 cal. Owing to its high S content (2.1-5.6%) and low calorific value, it has no economic importance at present.

R. L. SIBLEY.

Coal from Somaliland. ANON. *Bull. Imp. Inst.* 13, 189-90(1915).—Analysis of a sample of coal from Somaliland showed a calorific value about 75% of that of Welsh steam coal. It burned to a light, cream-colored ash which did not fuse.

R. L. S.

Predetermination of the clinkering action of bituminous coals by laboratory tests. F. C. HUBLEY. *Proc. Eng. Club Phila.* 32, 35-85(1915).—Fusion tests were made of ash cones in a gas-fired Fletcher crucible furnace, the furnace being held 3 min. at the temp. where the cone began to lose its sharp sides or to swell. 4-5 cones of the same ash mixt. were then heated within a range of 100-200° on either side of the preliminary test, from which an arbitrary point was taken at which fusion occurs. On account of time required for cone detns. a "fusiometer" was designed; in this a pellet of coal formed under pressure was subjected during the furnace run to a load of 1.5 lbs. per sq. in. by means of a weighted C rod. The vertical movement of the C rod was magnified 12 times on a horizontal scale and the results plotted using temps. as abscissas and scale movements as ordinates. Sixty-mesh ash was used and temps. measured with a Pt-Rh thermocouple standardized against the m. p. of Cu and Ni cylinders under 1.5 lbs. pressure. The results showed that a long range ash with slow increase in softening produced a close, gummy clinker of high viscosity, with corresponding max. clinker formation in boiler firing; the other type is a short range, spongy, porous formation of low viscosity which is handled more easily under a boiler. Wide variations were found in viscosity between ashes fusing at approx. the same temps. Attempts to correlate the fusion point with the ultimate analysis were made; Fe appeared to be the most potent flux while no relation was found between fluxing point and CaO or S content. Prost's formula and the "F" modulus were applied with variable results; better agreement was obtained with the "H" modulus, in which fusion is made proportional to 100% minus SiO₂ and inversely proportional to the product of SiO₂ and Fe. A max. temp. error of 160° F. was obtained in this way. Fusion ranges of various ash constns. were made, from which it is concluded that any combination of SiO₂ and Fe in the fuel bed is probably in the form of ferric silicate (cf. Fieldner and Hall, *C. A.* 9, 1837-8). Variations of fire box temp. with rate of combustion or boiler load tests, causes the adoption of a specification requiring the application of a load of 1.5 lbs. per sq. in. and a fusion temp. not under 1482°. The curve from the fusiometer develops fusing range, m. p. and viscosity of melt and if lower fusing point is specified the viscosity of melt must be considered. Duplicate results may be obtained within 10° and the time required averaged 26 min. per test.

A. J. PHILLIPS.

Four points in the indictment of the smoke nuisance. JOHN O'CONNOR, JR. *Pop. Sci. Monthly* 87, 244-9(1915).—A statement of our present knowledge of the:

effects of smoke on (1) building materials, (2) meteorological conditions, (3) vegetation and (4) health. E. J. C.

Blast-furnace gas in steam production. S. M. MARSHALL. *Iron Coal Trades Rev.* 91, 45(1915).—Top gas may be classed under 3 heads: (1) waste, (2) that required for stoves, and (3) the remainder available for power. In well constructed plants waste is about 6%, stove consumption 24-30%, leaving 64-70% for blower and surplus power. The variation in the vol. and pressure of the top gas due to the checking of the blast in casting, prevents high efficiency in burning the gas. M. describes a regulating device for the burner, by the use of which boiler efficiencies are raised from 57 to 80%. H. L. OLIN.

The Morgan producer-gas machine. *Iron Age* 95, 1161-3(1915).—3000 lbs. coal per hr. are gasified. The fire bed is not stirred, but leveled and ashes removed at bottom once a day. The blast is evenly distributed by 3 hollow arms, and a pipe extending around the mantel. The walls are made thin so that water-cooling is effective on brick, preventing slagging action. Using 2,766 and 3,200 lbs. coal per hr. gives gas of following, resp., compn.: CO_2 , 2.8, 3.0%; C_2H_4 , 0.6, 0.9; CO , 27.3, 29.5; H_2 , 11.1, 11.8; CH_4 , 3.4, 2.6; B. t. u. total at 0° 179, 186. One-sixth lb. steam per lb. coal is required for power. H. V. MAIN.

The coking of coal at low temperatures with special reference to the properties and composition of the products. S. W. PARR AND H. L. OLIN. Univ. Ill. Eng. Expt. Sta., *Bull.* 79, 39 pp.(1915).—Coke resulting from the low temp. process contains from 18% to 22% volatile matter but retains no tar-forming constituents. In domestic appliances it kindles readily and burns with a bright, smokeless flame. A suction gas-producer test made with this fuel compared favorably in ease of operation and efficiency with similar tests of anthracite. The tar (d. = 1.069) contains less than 2% free C and is rich in low-boiling substances, many of which are suitable for use in internal-combustion engines. Tar acids (phenol, cresols, etc.), useful for preserving wood, constitute 30% of the crude material. The pitch residue, 30%, is low in free C. Naphthalene is absent. E. J. C.

Coking coal chain stoker. *Iron Age* 95, 1280-1(1915).—The Green Eng. Co. provide an inclined, agitated coking grate which permits the volatile matter to be distd. and burned. This grate deposits the coked coal on the chain grate. H. V. MAIN.

Utilization of waste sulfite liquors (LANDMARK) (RINMAN) 23. Stoking with bagasse (PRINSEN-GEERLIGS) 28.

U. S., 1,148,368, July 27. E. V. EVANS. Recovering nitrogen as ammonium salt from the hydrocyanic acid of coal gas by first converting the HCN into NH_4CNS soln. of about 20-30% strength and then heating this soln. to 80-110° with 1.5 times its vol. of H_2SO_4 of 70-80% strength. The resulting liquor is introduced into the saturator in which the ammoniacal liquor from the gas is distd.

U. S., 1,148,403, July 27. R. D. PRICE. Mixture for removing carbon deposits from internal combustion engine cylinders, formed of alc. 25, graphite 1, CS_2 25, kerosene 25 and lubricating oil 24%.

U. S., 1,149,536, Aug. 10. H. J. PHILLIPS and A. PHILLIPS. Coal briquets are made by grinding coal to a pulp with 45-60% its wt. of H_2O , molding under sufficient pressure to remove part of the H_2O , heating the formed briquets to 200-500° and then pressing again after heating sufficiently to slightly soften the briquet.

Brit., 9,034, Apr. 9, 1914. W. B. DAVIDSON. Recovering pitch by fractional distn. of the tar in the hydraulic main of a gas plant by agitating the tar so as to cause constant change in the surface of the tar exposed to the hot gases passing therethrough. The pitch delivered by the dip-pipes or deposited by the gas is kept in soln. with the tar, and the formation in the main of solid pitch is prevented. Tar from the condensers, etc., may be introduced into the main. The agitation may be produced by gas jets, steam within limits, or by mechanical devices such as an archimedean screw.

Brit., 9,040, Apr. 9, 1914. G. H. BENTLEY and E. G. APPLEBY. To prevent caking of the fuel and the formation of clinker in gas generators, and to secure a large

gasification, the shell of the generator is given a rising and falling motion and is also revolved eccentrically around the grate. The grate may be revolved in the opposite direction to the casing.

Brit., 9,302, Apr. 15, 1914. W. B. DAVIDSON and A. J. LIVERSEDGE. Constructional modifications of gas-washing apparatus of the type wherein a vertical rotating shaft passes through a number of superposed compartments, through which gas passes upward and carries in each compartment sprayers and means for supplying liquid from the bottom of the compartment to the sprayers.

Brit., 9,587, Apr. 17, 1914. R. C. CONGDON. A stand-pipe for gas retorts, of the kind in which the gas passes upwards and a stream of liquid descends, is formed in one piece extending above and below a series of retorts, to which it is connected by short pipe lengths.

22. PETROLEUM, ASPHALT AND WOOD PRODUCTS.

F. M. ROGERS.

Motor fuels. V. B. LEWIS. *J. Roy. Soc. Arts* 63, 757-63, 773-80, 792-9(1915).—Lectures covering production, compn., properties, uses, and performance of petrol and petrol substitutes. Cf. *C. A.* 9, 1244. F. W. SMITHER.

Petroleum in Papua. ANON. *Bull. Imp. Inst.* 13, 185-9(1915).—A crude petroleum from the Vailal River region which consisted of a reddish brown, mobile oil, showing a bluish fluorescence and depositing a slight sediment of clayey matter on standing, was examd. and found to have $d_{40} 0.802$, and a flash point below 20° . Fractional distn. showed that 32.5% boils under 150° , 58.7% from 150° to 300° , and 8.8% over 300° . The oil is unsatisfactory for use as fuel oil for it has a low flash point and deposits solid paraffins at ordinary temp. The sample contained a high proportion of light petroleum and kerosene but the results are not very reliable for the sample was obtained from a shallow boring. R. L. SIBLEY.

Red charcoal from hop vines (REINKE) 23.

U. S., 1,150,589, Aug. 17. E. H. FRENCH. In the destructive distillation of wood the vapors are fractionally condensed to liquefy and sep. a portion of the tars and oils, then the tars and oils left suspended in the vapors are removed by centrifugal action and the condensable constituents are then condensed to obtain pyrolygneous acid.

Brit., 9,088, Apr. 9, 1914. SOC. E. BARBET ET FILS ET CIE. App. for the continuous fractional distillation of petroleum, benzene, etc., by passage through a series of bulk evaporators, maintained at successively increasing temps. and under the same pressure, is so arranged that the vapors generated in an evaporator working at a higher temp. are employed for heating the evaporator at the next lower temp., the vapors being made to circulate below the evaporator heated by them in the opposite direction to that taken by the liquid circulating in that evaporator.

23. CELLULOSE AND PAPER.

A. D. LITTLE.

Process for toughening ordinary filter paper. WILLIAM R. RANKIN. *Pharm. J.* 95, 36(1915).—Best English filter paper is dipped very quickly into conc. HNO_3 (d. 1.42), drained rapidly, placed in running H_2O and then immersed in 0.5% NH_4OH until all acid is neutralized. Wash well in running water, drain, and dry partially between blotting paper, then in water oven at 100° . When dry, the process is repeated,

and when finally dried, the paper will be ready for use. The linear shrinkage is about 9%. Drying above 100° would cause decompn. of nitrated cellulose, giving off pungent fumes.

S. WALDBOTT.

Waterproofing of paper. H. WANDROWSKY. *Papier Ztg.* 40, 500-1, 524-5, 579-80, 597-8, 615-6, 653-4(1915).—Waterproofing is dependent upon the destruction of the capillarity of the paper. It may be accomplished by 3 general methods: (1) impregnating the paper with a water resistant material; (2) spreading on the paper a resistant surface coating; and, (3) impregnating the separate fibers before forming the sheet. For impregnation, a variety of waxes, oils and varnishes is used, notably paraffin. The nature of the reagent used depends on the purpose to which the paper is to be put, crude ozokerite, *e. g.*, being used for certain low grade papers and fine beeswax being often employed in case the paper is to be used in direct contact with food products. Impregnation is accomplished by passing the paper through a bath of the reagent maintained about 10° above its m. p., excess being removed by squeeze rolls. For waterproofing of the separate fibers, Al acetate formed by decompn. in the web of Al sulfate by means of Pb acetate, or better by Ca acetate, is commonly employed. A well closed paper without filler is preferably used. Drying temp. after impregnation should not exceed 38°. Soaps of alumina behave similarly to the acetate. Papers treated by Al soap or Al acetate are water-resistant but are permeable to air. To obtain complete impermeability, impregnation by an emulsion of rubber, carnauba wax, paraffin, rosin and potash soap is recommended. To waterproof paper by surface coating with water-insol. reagents, glue after-treated by CH₂O or dichromate and casein after-treated by lime are recommended. Such surfacing, however, does not guard against edge penetration. Pptn. upon the fibers of certain metallic oxides, notably those of Fe and Al also has a waterproofing effect. The action upon cellulose of cuprammonium, ZnCl₂, and of long-continued beating is briefly touched upon. Technical operating hints are freely given and a brief bibliography is included in the article.

V. NUNEZ.

Preparation of rosin sizing. LEO SCHLICK. *Paper* 16, No. 8, 13-5(1915).—For most efficient sizing, rosin should be saponified with the least possible amt. of alkali. Sapon. should be slow and at const. temp. Use of soft water is important. The heat of the driers on the paper machine plays an important part in sizing.

V. NUNEZ.

Sizing paper with gelatin. F. CYSTER. *Chem. Eng.* 22, 23-5(1915).—All-cotton paper, engine-sized with 2.5% rosin size, absorbed about half as much gelatin, when tub-sized, as waterleaf paper, the intermediate points (2.0%, 1.5%, etc., rosin size) deviating slightly from a straight line curve. Gelatin size prepared without alum has considerably greater penetrating power than the usual gelatin size, but the paper made with it is less ink-resistant and has less rattle.

V. NUNEZ.

Utilizing cotton stalks. W. C. OLDS. *J. Roy. Soc. Arts* 63, 580(1915).—A paper mill to use cotton stalks as raw material is projected at Greenwood, Miss., U. S. A.

V. NUNEZ.

Manufacture of fiber, paper and red charcoal from hop vines. OTTO REINKE. Braunschweig. *Chem. Ztg.* 39, 597(1915).—Long weathering gave 20% of fiber of good quality. The residue treated with 6% NaOH soln. at 3 atms. pressure gave an excellent pulp. The roots also yielded a beautiful long-fibered, white material. Dry distn. at 330° gave a fine charcoal.

J. H. MOORE.

Papers with woven inlay. ANON. *Papier-fabrikant* 13, 197-201(1915).—Such papers are generally made by pasting a layer of woven fabric between two liners of paper. A slightly absorbent, rough finish paper, subject to but small dilation with increase in moisture, is desirable. Potato starch is the usual adhesive, the paste being

applied to both paper and fabric. The product is generally supercalendered and if desired is waterproofed by gelatin and lead acetate.

V. NUNEZ.

Causes of defects in sulfite cellulose. R. R. OLIVER. *Chem. Eng.* 22, 27(1915).
—Various causes of dirt in sulfite pulp are briefly referred to.

V. NUNEZ.

Utilization of waste sulfite liquor with especial reference to alcohol production. H. B. LANDMARK. *Papier Ztg.* 40, 495-6, 519-20(1915).—In the Landmark process a small amount of milk or whey is mixed with an equal vol. of waste sulfite liquor and warmed to 50° with HCl. The pptd. "ligno-casein" (a yellow powder, sol. in alk., and suitable for paper size) is separated and the filtrate added to the main vol. of waste liquor. The whole is then partially evapd.; this served the double purpose of driving off the free SO₂ from the liquid and of hydrolyzing the milk sugars. The easily fermentable sugars thus formed have a highly beneficial effect on the fermentation of the waste liquor. After neutralization of the residual traces of SO₂, by means of CaCO₃, the mash is fermented for 4 to 5 days with about 1/2% ordinary brewers' yeast. Yields of about 88 liters abs. alc. per ton cellulose are claimed at a production cost of 13 to 14 ore (3 1/4 to 3 1/2 cents) per liter. These figures are considerably better than the corresponding claims of the Ekstrom process. The alc. obtained is not potable since it contains a considerable % of MeOH but it is excellently suited for fuel or motor spirit. The liquor during the process has been concd. about 25% and after fermentation may be economically concd. for fuel, the "cell pitch" thus obtained having a fuel value of 3500 cal. "Cell pitch" per ton of cellulose is equiv. in fuel value to 372 kg. good steam coal. Concd. and dry distn. by the Strehlenert process is also possible.

V. NUNEZ.

Utilization of sulfate and sulfite waste liquors. E. L. RINMAN. *Papier Ztg.* 40, 559-60, 574-5(1915).—Application of the Rinman process to recovery of values from sulfate black liquor is meeting with some difficulties in practice particularly as regards dry distn. The general procedure is to add soda to the black liquor, causticize with lime, filter and conc. to 35° Bé. To the thick liquor are added 3/4 mol. Ca(OH)₂ (calcd. on Na₂O content of the original black liquor), the whole further conc. and finally subjected to dry distn. Presence of NaOH induces high yields of MeOH from the constituents containing methoxyl of the black liquor and presence of lime induces high yields of Me₂CO from those constituents which do not contain the methoxyl group. A modification of the Rinman process is applicable to sulfite waste liquor. The liquor is heated 5 hrs. at 180° with lime, the ppt. of CaSO₃ and humus separated and the CaSO₃ dissolved out by SO₂, the liquor thus formed being used in the cooking process. The residual humus serves for fuel. The liquor is concd., more lime added and the whole brought to dryness and distd. in the presence of water vapor. Sawdust may be added to the liquor prior to the heating with lime and is advantageous in increasing yields and ease of filtration. The liquor may be fermented prior to concn. The process is now in operation at Skutakär, using as raw material equal vols. of spent wash from alc. fermentation of sulfite waste liquor, and sawdust, with high yields and good results.

V. NUNEZ.

Inactive borneol formed by sulfite cooking. H. BERGSTRÖM. *Papier-fabrikant* 13, 229-31(1915).—When MeOH is distd. from waste sulfite liquor a heavy oil is obtained toward the end of distn. from which optically inactive borneol may be crystallized on cooling.

V. NUNEZ.

U. S., 1,149,420, Aug. 10. R. W. STREHLENERT. Separating organic and inorganic constituents of waste sulfite liquor. The free and combined SO₂ is oxidized into H₂SO₄ by the action of air or O under heat and pressure and the H₂SO₄ as fast as

formed is allowed to act on the other constituents, in the presence of NaHSO_4 , which is added to retard the reaction, to cause pptn.

Ital., 134,462, Sept. 24, 1913. E. BERT. In the manuf. of cellulose products, a soln. of cellulose is prepared by means of H_2SO_4 of 77% at a temp. not exceeding 10° . The soln. is pptd. with 50% alc. at 20° .

24. EXPLOSIVES AND EXPLOSIONS.

C. E. MUNROE.

Liquid air as an explosive. M. PRYZBORSKI. *Z. Eis u. Kalte Ind.* 7, 93(1915).—A dry cardboard cartridge contains a perforated pipe, in which is a mixt. of infusorial earth with oil, asphaltum or lampblack and paraffin. A third inner tube serves as an exhaust for the volatile products. The liquid air is poured in the central tube. The charge ignites by a spark with a violent explosion. If the spark misses the air evaps. A. J. PHILLIPS.

U. S., 1,149,487, Aug. 10. C. A. WOODBURY. An Explosive formed of nitrated sugar 4%, nitroglycerin 30%, trinitrotoluene 10%, NaNO_3 42%, wood meal 13% and chalk 1%. The nitrated sugar gives the mixt. a low freezing point. Cf. C. A. 9, 717.

U. S., 1,149,585, Aug. 10. C. R. JAHN. Denitrating waste acid from making trinitrotoluene, etc. See fig. The waste acid is evapd. and the organic substances are removed from the gas and vapors by passing them through the pipe 2 over a body of H_2O 3 in the chamber 4. Part of the HNO_3 is absorbed by the H_2O and that remaining passes off through the pipe 8 to a condenser. The solidified organic compds. settle out in the chamber 4.

25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

The manufacture of organic coloring substances. WAHL. Univ. Nancy. *Bull. soc. encour. ind. nat.* 122, 492-509(1915).—An address of a historical and statistical nature. H. I. OLIN.

The mechanism of the acid dye bath. II. M. FORT AND D. SWARES. *J. Soc. Dyers, Colourists* 31, 80-3(1915).—In Part I (C. A. 8, 3720) it was shown that wool absorbed H_2SO_4 which it later split off into the dye bath when an acid dye was absorbed, it being found that with both dye and acid in the bath more dye was taken up by the wool and less acid. The effect on the exhaustion of an acid bath by adding an acid dye has been overlooked although the converse has been well established. The present paper shows by comparative expts. that both color acids and acid dyes as salts, when used along with H_2SO_4 in the dye bath, cause an excess of H_2SO_4 to be left in the dye bath at the finish over what is left when the H_2SO_4 is used alone. It is also shown that dye and acid interfere with the exhaustion of each other when used together in the ordinary dye bath. It seems likely that the conception of additive salt formation between acid and wool fiber, is necessary to obtain a satisfactory theory of any dyeing or chemical process in which the action of acids upon animal fibers or

tissues is involved. Bleeding tests show that the presence of H_2SO_4 in the wool almost entirely prevents bleeding for a day or two when subjected to the continued action of water, but when the water has removed the H_2SO_4 the bleeding goes on rapidly. III. M. FORT AND P. ANDERSON. *Ibid* 96-100.—As in the previous work sets of 3 comparative trials were made in reflux condensers with (1) H_2SO_4 , (2) dye-stuff, and (3) dyestuff and H_2SO_4 , but with modifications to improve upon the accuracy of previous expts. It is now possible to express chemically the aid rendered to dye absorption by acid. Results are in agreement with the following reaction representing the specific combination of dye, crystal scarlet, with H_2SO_4 : wool basic hydrate- $\text{H}_2\text{SO}_4 + \text{C}_{20}\text{H}_{12}\text{N}_2\text{O}_2\text{Na}_2 \rightleftharpoons \text{wool basic hydrate} \cdot \text{C}_{20}\text{H}_{12}\text{N}_2\text{S}_2\text{H}_2 + \text{Na}_2\text{SO}_4$. This reaction may be reversed by treating the dyed fiber with Na_2SO_4 when stripping occurs. The common assumption that H_2SO_4 in the dye bath first liberates the free color acid is not supported by the results of F. and A. The following conclusions are drawn from the tabulated results: (1) The increased amt. of SO_4 found in the exhausted dye bath over that left in the exhausted acid bath containing no addition of dye is not enough to account for the production of Na_2SO_4 by interaction of the total dye used with H_2SO_4 . (2) The increased amt. of SO_4 found in the exhausted acid dye bath bears a simple relation to the extra dye caused to be taken up by the wool from the bath by the use of acid, *i. e.*, over and above that dye absorbed from a similar neutral bath. (3) One factor which precludes the attainment of theoretical results is the alteration in acid distribution between fiber and soln. which necessarily accompanies the formation of Na_2SO_4 and affects to some extent the quantity of SO_4 in the dye bath. (4) There is no reason for supposing that the case of crystal scarlet presents any unusual features which might render the result of individual and not general interest.

L. A. OLNEY.

The reeling of Tussar silk. ANON. *Bull. Imp. Inst.* 13, 101-2(1915).—Before reeling Tussar silk the cocoons must be boiled in an alk. liquid. The natives add the ashes of plantain leaves to water and boil the cocoons in this for 2 or 3 hrs.; they then leave them to ferment for some hrs. before winding. In some factories in Bengal, the cocoons with their stems cut off, are tied up loosely in a cloth; this is weighted down with stones and boiled for $\frac{1}{2}$ hour in a soln. contg. 3 parts of K_2CO_3 dissolved in 80 parts of water, oil and sugar being sometimes added. The cocoons are afterwards boiled for a few min. in water contg. a little glycerol. The silk is then reeled. The glycerol keeps the cocoons moist while reeling, and it is not then necessary to keep them in basins of water during this operation. Another method is to prepare a fine powder or paste from the chrysalides of tussar or mulberry insects; about one part by wt. of this is mixed with 2 parts by wt. of dry cocoons and the mixt. is tied up in a cloth, weighted, and immersed in water, which is then boiled for an hour. The mixt. is next left to ferment for 12 hrs., after which reeling begins, the cocoons being allowed to rotate in basins of hot water just as when mulberry cocoons are reeled. The reeled silk obtained by any of the above processes must next be immersed in a warm acid soln., then washed in a bath of boiling soap or washing soda soln., and finally rinsed in boiling water, wrung, dried, and baled for export. The acid bath can be prepared from tamarinds, using 1 part by wt. of tamarinds in water to every 4 parts by wt. of tussar thread.

is made by coupling the tetraazo deriv. of *m*-aminophenylazo-2,5,7-aminonaphthol-sulfonic acid with 2 mol. proportions of resorcinol. Its alkali metal salts are dark red powders sol. in hot H_2O and dye cotton claret-red rendered fast by treatment with CH_3O .

Brit., 8,919, Apr. 8, 1914. H. KRANTZ. App. for dyeing, wherein hanks and skeins, instead of being threaded on rods or carriers, are suspended on them by folding, so that their median portion rests at 2 points on them, and their ends hang down in the form of loops on each side. Arresting planes or surfaces, perforated or not, are mounted above the hanks in the known manner.

Brit., 9,052, Apr. 9, 1914. N. WOSNESSENSKY. In dyeing or printing with basic dyes, the dyes and tannin are applied together in presence of resorcinol as solvent. The Sb salt may be applied simultaneously or subsequently. Examples are given of (1) a padding bath containing methylene blue, tannin, resorcinol, HOAc, and H_2O , the material being padded, steamed, and then treated with Sb salt, and (2) a printing-paste containing methylene blue, tannin, resorcinol, HOAc and tartaric acid, tartar emetic, and starch-tragacanth thickening, the material being printed and then steamed.

Brit., 9,102, Apr. 9, 1914. CHEM. FABRIK GRIESHEIM-ELEKTRON. Dyeing or impregnating cotton goods with azo dyes, with the aid of a soln. or paste containing a nitrosamine salt and an aryliide of 2,3-hydroxynaphthoic acid, and development by passage through a bath of a weak acid or an acid salt.

Brit., 9,252, Apr. 14, 1914. BAYER & Co. The azo dyes prepared from diazo compds. and acetoacetic esters are saponified, converted into the acid chlorides by treatment with thionyl chloride, PCl_5 , etc., and these converted into amides by condensation with aliphatic or aromatic mono- or di-amines.

Brit., 9,269, Apr. 14, 1914. FARBW. v. M. L. & B. Vat dyes of the dihydro-1,2,3',1'-anthraquinoneazine series are converted into a finely divided or amorphous form by treatment with H_2SO_4 under such conditions that the dye remains undissolved either as free base or as sulfate; if the sulfate is formed, it is dissociated by adding H_2O . If crude vat dye is treated by the process, it may be simultaneously purified from flavanthrene, etc., which dissolve in the acid. Suitable dyes for treatment are indanthrene RS or GC, the crude vat dye obtained from the alkali melts, or the coarsely subdivided forms obtained by blowing air into a vat of the dye, or by dissolving the dye in H_2SO_4 and pptg. with H_2O . The process can be carried out by treatment with a suitable quantity of H_2SO_4 monohydrate, forming H_2SO_4 , or acid of 60–66° Bé., and then dissociating the sulfate with H_2O ; or a weaker acid may be used which does not yield the sulfate, and the sepd. dye then washed free from acid; or highly concd. acid may be first used and the mass be then dild. with a little H_2O , so that the impurities remain in soln., while the dye or its sulfate is sepd. The production of the finely divided state may be assisted by the addition of aromatic acids, Na benzylsulfanilate, etc.

Brit., 9,433, Apr. 16, 1914. KALLE & Co. A dye that dyes wool blue shades from acid baths is obtained by fusing 1-naphthylamine-4,8-disulfonic acid with re-

ducing compds. of S in the presence of alkali; reducing-gases (SO_2 and H_2S) or their compds. are removed from the reaction product before pptn. of the dye. This is effected either by dissolving the melt in H_2O , and pptg. insol. compds. of these gases from the alk. or neutralized soln., or by acidifying and blowing in air; the latter process may also be employed subsequently to the pptn. process. The dye is finely pptd. by making the soln. neutral or alk. and heating it or blowing in air. The same process of working up the melt may be applied to the product obtained from 1-naphthylamine-3,6,8-trisulfonic acid described in 17,610, 1907. Suitable precipitants for the H_2S are FeSO_4 or FeCl_3 , and for the SO_2 , CaCl_2 or BaCl_2 . **Aminonaphtholsulfonic acids** are obtained as by-products in the above processes, and are pptd. on acidifying the solns.

Brit., 9,471, Apr. 16, 1914. **BAYER & Co. Dyeing coarse grained or finely powdered vegetable or animal substances, e. g., wood meal, leather shavings, and cork meal, by spraying with dyestuff soln. while they are kept in motion, so that the particles are continuously brought to the surface, or a fresh surface is continuously presented to the dye soln., which is sprayed in as concd. a form as possible.** This may be effected in an app. comprizing a double-walled drum rotating about a horizontal shaft, and capable of being heated, which is provided in its interior with a pipe having nozzles for the injection of the dye soln. The drum is about one-fifth filled with the material to be dyed and, while it is in motion, the concd. soln. is injected through the nozzles. Drying is effected in the same app., hot compressed air being blown in.

Ger., 283,232, Apr. 3, 1913. **W. MATHESIUS and M. FREIBERGER. Reviving the scalding tank liquors.** These liquors contain the alkali employed only in part in the original form, while a great part is converted into salts of the fatty acids. Furthermore, impurities have been taken from the textile material. According to this process these dirty liquors are purified for re-use by first destroying the dye substances of the lyes by treatment with a hypochlorite. The clearing of the lyes can be furthered also by a reducing treatment, in that by treatment with sulfites those substances which have resulted from the oxidizing action of the hypochlorite are destroyed. Any residue of hypochlorite is destroyed also. Before the treatment with hypochlorite and sulfites, the lyes are treated with $\text{Ca}(\text{OH})_2$, whereby the pptg. insol. Ca-compds. carry down suspended matter. This action can be favored by the addition of clay, as well as metal salts, which form voluminous ppts. (e. g., $\text{Fe}(\text{OH})_3$). E. g., 80 kg. $\text{Ca}(\text{OH})_2$ are added to 5000 liters of used lye, the mass is boiled, allowed to settle, the soln. is drawn off, and so much NaOCl is added that about 1 g. active Cl is present to 1 liter. The mass is heated again and then 3 liters NaHSO_3 soln. of about 35° Bé. are added. The regenerated liquor has a light yellow appearance and contains the Na in the main as free NaOH .

E. W. BOUGHTON.

The nature of American rosin. L. PAUL. *Strassburg. Seifensieder Ztg.* 42, 237-8(1915).—On the strength of some elementary work on com. rosin (cf. *C. A.* 8, 2626, 3379; 9, 972) P. claims that all former investigators have misjudged the true nature of rosin and that his work shows beyond doubt that American rosin contains up to 90% of a constituent called by him KS ("Kolophonium schwer löslich"), which has 2 m. ps., 70-71° and 76-77°; the remaining 10% consists of "KI," which is said to be a mixt. of a gum with a whole series of resins difficult to sep. from one another, and a small quantity of "KLM" which is left in soln. in the acid filtrate when rosin is salted out by excess of Na_2CO_3 and the Na_2CO_3 mother liquor decompd. by some acid.

P. ESCHER.

The abietic acids (POOTH) 10.

U. S., 1,149,171, Aug. 10. C. BAEDER. Insulating-varnish is formed of raw linseed oil 100 gals., refined para rubber 25 lbs., Mn borate 10 lbs., calcined sugar of lead 75 lbs., and turpentine 50 gals., mixed with additional thinner and Japan drier.

U. S., 1,149,519, Aug. 10. A. C. HORN. A plastic composition for waterproofing walls, etc., is formed of mineral filler or pigment mixed with Chinese wood oil which has been slightly vulcanized by heating to 205° with about 3% its wt. of S.

U. S., 1,150,516, Aug. 17. H. J. GREENE. Priming paint for wood, formed of white lead 100, ZnO 50, SiO_2 100, linseed oil 180, drier 10, turpentine 10 and C_6H_6 or xylene, or a mixt. of both, 30 parts.

Brit., 9,291, Apr. 14, 1914. L. V. REDMAN. A fusible resinous product is obtained by condensation of phenols with hexamethylenetetramine in the absence of H_2O , the proportion of phenol used being such that the resin contains more than 25% of free phenol. The process may be effected by heating the mixt. until self-heating occurs, allowing the reaction to proceed by self-heating only until the evolution of NH_3 slackens, and again applying heat until all the NH_3 is driven off. The NH_3 evolved may be collected and converted into hexamethylenetetramine for reuse. The product is converted into an insol., infusible product by treatment with suitable methylene compds., e. g., hexamethylenetetramine, HCHO , or HCHO and NH_3 . Fillers, such as kieselguhr, silica, powdered slate, stone, asbestos, wood fiber, or cellulose, may be added before the final step; the product may be colored by suitable dyes. The resinous product may be employed as a varnish, and the infusible product for elec. insulation.

Brit., 9,333, Apr. 15, 1914. E. BARTHELMESS. In the manuf. of lead oxide by the action of a stream of gas containing O upon atomized Pb, the H_2O necessary is added drop by drop in measurable quantities to the stream of gas, which is sucked into the oxidizing chamber.

Brit., 9,368, Feb. 15, 1913. P. FERRERE. Zinc oxide is prepared by burning Zn vapor as it issues from a retort in a burner supplied with air and steam.

27. **FATS, FATTY OILS AND SOAPS.**

R. SCHERUBEL.

New method for determining the melting point of solid fats. ROMOLO ROMANELLI. Arezzo. *Giorn. farm. chim.* 64, 151-3(1915).—A thermometer held in position by a cork is inserted into a 250 cc. flask. One end of a Pt wire is twisted around the bulb

of the thermometer and the other end is bent in a circle 8-9 mm. in diam.; the wire is bent in such a direction that the diam. of the circle is parallel to the stem of the thermometer. The flask is filled with distd. H_2O and the latter is boiled so as to expel dissolved air as well as air bubbles which are attached to the surface of the thermometer and inner surface of the flask. A portion of the fat to be examd. is then slowly melted in another vessel and allowed to cool at a temp. near the m. p. The wire loop mentioned above (detached from the thermometer) is then immersed in the liquid parallel to the surface of the latter and quickly withdrawn so that a thin film of fat remains within the loop. Some practise may be required in order to accomplish this readily. The film of fat is allowed to cool for 1 hr. The wire loop with film is then attached to the thermometer and the latter is inserted in the H_2O in the flask which is heated by a flame. As the temp. of the H_2O approaches the m. p. of the fat a transparent zone is observed at the periphery of the film. The temp. observed at the moment when the film becomes transparent throughout and breaks is the m. p. of the substance.

H. S. PAINE.

Rancidity of fats. HENRY L. SMITH. *Pharm. J.* 95, 4-5(1915).—A summarizing discussion. Rancidity does not run parallel with acidity. It may be induced by enzymes and microorganisms. The odor is due to extremely small amts. of ketones and aldehydes. To prevent rancidity, keep fats as free as possible from H_2O , shielded from light, and in minimum contact with air. In rancid fats, hot H_2O will remove sol. fatty acids; soln. of $KMnO_4$ is very effective in oxidizing aldehydes and ketones, and Na silicate will remove free acids, Na_2CO_3 in this case would produce emulsions.

S. WALDBOTT.

Fat conservation. J. LEIMDORFER. *Seifensieder-Ztg.* 42, 281-3, 303-4, 321-3, 343-4(1915).—A discussion of measures taken in Germany to conserve fats. E. S.

Oxidation and polymerization of soy bean oil. N. J. A. TAVERNE. *Z. angew. Chem.* 27, I, 249-51(1915).—Oxidation in the air at room temp. was carried out by Fabrian's method. The hydroxy acids of 3 g. of oil on 10 g. of cotton yarn were detd. after 30 days' exposure and found to be 38.4%. Oxidation at 70° was carried out in the app. of H. Genthe (*Z. angew. Chem.* 19, 2087) and was complete in 30 hrs. Oxidation in air at 150° was also carried out according to Genthe, by heating in a beaker. The mol. wt. rose in 10 days from 710 to 1730, a fact which indicated polymerization or condensation along with the oxidation. The oil became solid and contained 31.8% hydroxy acids and 63% fatty acids sol. in petroleum ether. The I no. decreased to 64.8. Heating for 14 days at 135° gave a thick oil of d_{16} 0.9588 with 27.2% hydroxy acids, and 66.5% fatty acids. I no. was 65.7. It is possible that soy bean oil can be used in the linoleum industry. Genthe states that siccative are inactive in the ultraviolet rays but T., on the contrary, obtained complete oxidation in 45 hrs. A Pb-Mn rosin compd. contg. 6.28% Pb and 5.76% Mn was found to be the most active agent for hastening oxidation. In the ultraviolet light at 70° oxidation was complete with 5% siccative in 580 min. Soy bean oil is readily polymerized, though not to so great a degree as linseed oil. T. heated 20 small flasks supplied with capillary stoppers in powdered graphite in an air bath at 150°; the mol. wt. and I no. were detd. daily in one of these. The I no. decreased from 137.5 to 90.5 but the mol. wt. remained const., and the oil remained liquid. Heating at 200° gave similar results. By adding 30% of linolic acid to the oil and heating to 250° the I nos. were reduced but the oil remained liquid. When heated to 300° the oil became solid in 12 days and after 17 days it was insol. in benzene. At the end of 10 days' heating at 300° the mol. wt. rose to 1200. By adding 1% oxidized soy bean oil to fresh oil and heating to 300° the mass became solid in 7 days.

E. SCHERUBEL.

Frugal use of lubricating oils. FR. WISSAWE. Cologne. *Chem. App.* 2, 176-9 (1915).—General remarks on the use, recovery, and purification of recovered oils, and substitutes for mineral oils. J. H. MOORE.

Soap. HENRY I. SMITH. *Pharm. J.* 95, 33-4 (1915).—A discussion of the chem. and phys. nature of soap, including special com. soaps, *e. g.*, marine soap, shaving soap, etc., and adulterations. S. WALDBOTT.

Qualitative test for ox-gall in soaps. F. STEINITZER. *Chem. Rev. Fett-Harz-Ind.* 22, 69-70 (1915).—Ox-gall may be added to soaps fresh, or after concg. to $\frac{1}{8}$ its vol., or after boiling and the addition of 5% ethyl acetate at 80°, then skimming and settling. Its coloring power is weak; ultramarine green or brilliant green, etc., is usually added to the soap. Qual. test (Pettenkofer's): Dissolve 2-5 g. of the soap in 50 cc. warm H₂O and set aside to let any ultramarine settle; filter and decompose with dil. H₂SO₄. The gall acids are changed almost entirely into fatty acids. Any albumin is filtered from the melted acids. Allow to solidify and transfer to a wide test tube, add 10 cc. 1:1 H₂SO₄ and heat in bath to 65-70°. Add 3 drops of a 10% sugar soln., shake well for $\frac{1}{2}$ min. and return tube to the 70° bath. The presence of gall is shown by a red to violet-red color, its absence by a yellow or yellowish brown color.

P. ESCHER.

Glycerol yields. O. STEINER. *Seifenfabr.* 35, 28 (1915).—Owing to demand for glycerol on account of the war, it is advised that all soap manufacturers use one of the fat-cleavage processes for sepg. glycerol because of the higher yields. E. SCHERUBEL.

The solubility of water in essential oils (UMNEY) 17. Determination of peanut oil in olive oil (LUND) 12. Cane wax (CROSS) 28. American rosin (PAUL) 26.

28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

The limits of accuracy in saccharimetric analyses. C. A. BROWNE. *Intern. Sugar J.* 17, 320-6 (1915).—B. has carefully considered each individual error in order to det. whether the final error of polarization is always too high or too low. (I) *Loss of moisture during mixing.* Atmospheric conditions must be considered so that evapn. or absorption will not result. By rapid mixing on glass the loss was not greater than 0.01%. (II) *Loss of moisture during weighing.* This step can be controlled with a loss not greater than 0.005%. (III) *Error in normal weights.* The usual method of correcting a normal weight is found to be inaccurate. If a loss of 2 mg. is restored by unscrewing the cap of the weight and inserting wire or foil and this procedure is repeated later after another loss of 2 mg. the av. value of the normal weight is always 1 mg. too small. The better plan is to distribute the limits of error above and below the true value, the av. wt. being then exactly correct. If the normal wt. has become 2 mg. too light, it should be corrected by making it 2 mg. too heavy. When this method of correction is used, the error in normal wt. becomes self-compensating, and does not need to be considered in computing the final total error in a long average of polarizations. (IV) *Vol. of ppt. in clarification* has been found by investigators to show an error of about +0.09° S. for the av. raw cane sugar of 96° polarization. (V) *Pptn. of levulose in clarification* by basic lead acetate causes (by occlusion) an increase in the polarization, the error for the av. raw sugar of 96° test being about +0.015° S. (VI) *Capacity of flasks.* Care must be taken that in a given lot of flasks the errors of calibration are distributed equally above and below the true value of 100.00 cc. and should

never exceed 0.05 cc. The errors then become self-compensating and need not be considered in computing the final total error. (VII) *Imperfect mixing* of contents of flasks may cause an excess polarization amounting in some cases to several tenths of a degree, the final runnings of the imperfectly mixed soln. being more concd. since the first runnings of the dil. upper part are usually rejected. (VII) *Evapn. during filtering*. When the funnels are covered practically no increase in polarization results, although when a portion of the soln. is poured back upon the filter for refiltering the increase in polarization due to evapn. may amount to several tenths of a sugar degree. (IX) *Length of polariscope tubes*. As in the case of flasks, it is highly important in a given lot of tubes that the errors of calibration be evenly distributed above and below the true value of 200 mm., and should not exceed the limit of accuracy permitted by the U. S. Bur. of Standards of ± 0.04 mm., corresponding to an error of $\pm 0.02^\circ$ S. in the polarization of pure sucrose. (X) *Omission of dichromate cell*. This produces an increase in the polarization of sugars, the av. error according to Schönrock for normal solns. of pure sucrose being 0.115° S. It is less for raw sugar as the yellowish color of the clarified soln. itself acts as a light filter. The error is negligible in the case of molasses sugars and varies between $+0.05$ and $+0.10$ for the higher grades of centrifugal sugars. Sensibility to rotation dispersion might cause an error either way so that the dichromate cell is absolutely necessary to obtain uniformity and accuracy. (XI) *Variations of temp.* According to the calcns. of Schönrock a one-way difference of only 1° between the temp. of making up to vol. and the temp. of polarizing will produce a const. error of 0.061° S. The necessity of using the polariscope only when it has acquired the temp. of the lab. atm. is therefore very evident. B. recommends a normal temp. lab. controlled by a small refrigerating plant to maintain a temp. of 20° . (XII) *Defects in scales of saccharimeters*. For raw cane sugar the scale divisions immediately above and below the 96° point are of most importance. If the av. error at this point is $\pm 0.025^\circ$ S. the correction may be made by applying $\pm 0.05^\circ$ to each polarization on alternate days. If the av. error is only $\pm 0.01^\circ$ the correction may be made by applying $\pm 0.05^\circ$ to each polarization on every 5th day. In this way the av. polarization may be controlled to 0.01° without carrying each individual polarization beyond the half tenth required by trade usage. The most correct method for treating "split readings" is to make several readings on each tube and take the reading of greatest frequency as the correct polarization. Thus a sugar polarizing 96.02 would usually show 3 readings of 96.00 and 2 readings of 96.05 and the result would be entered as 96.00. The average of the polarizations so taken would then always be correct. It is highly important that the av. results of at least 2 chemists be taken and not the single test of an individual. The extension of an average to the 3rd decimal is accurate enough for most purposes and practical needs would rarely, if ever, require the carrying out of an av. beyond the 4th decimal figure. B. shows that of the 8 errors averaging $+0.48$, the last four which together cause a $+$ error of 0.20° S. are wholly preventable and that the first four are reducible. The magnitude of the final residual $+$ error under a carefully regulated control is estd. as follows for the av. raw cane sugar of 96° test, the error due to different causes being given in sugar degrees: evapn. in mixing $+0.10$, evapn. in weighing out $+0.005$, vol. of ppt. in clarification $+0.090$, pptn. of levulose $+0.015$, total $+0.120$; the difference of 0.36 between the total errors of 0.48 and 0.12 is not an extreme example. While the cause of these differences is usually to be found among the errors enumerated, there are often other factors, such as use of too much ether for dispelling foam, optical activity of tube glasses, and neglect of zero point error of saccharimeter, which is in itself an error of great influence. B. suggests that only by eliminating or reducing all sources of error can the art of saccharimetry be maintained at its highest level of efficiency.

A. Gross.

Conducting the determination of reducing sugars according to Allihn. J. PRITZKER. *Z. Nahr.-Gennussm.* 20, 437-8 (1915); *Schweiz. Apoth. Ztg.* 53, 409-11 (1915).—The well-known precautions to be observed in detg. sugar by Allihn's method are mentioned. The directions of von Fallenberg (*C. A.* 8, 835) were adopted. P. describes a simple rack by means of which the filter tube containing the Cu_2O can be kept in an upright position while drying in a steam oven. By treating the well washed ppt. 3 times with alc. and once with ether and then drying for 25 min. in an upright position in a steam oven all moisture is removed, thus eliminating a common source of error in the detn. Prolonged heat will oxidize Cu_2O . A. F. SEEKER.

The determination of sugar in bagasse. H. PELLET. *Intern. Sugar J.* 17, 327-8 (1915).—P. uses a modification of the Norris method (*C. A.* 5, 1002). A fairly strong Cu basket of perforated Cu plate is placed in the interior of the app. to hold the bagasse. At the completion of the detn. the basket is placed in a screw press and the liquid removed from the bagasse and added to the main portion. In order to read directly the % of sugar in the product, the wt. of the bagasse used and the vol. of the liquid (including the water added, and that in the bagasse) have been modified. The liquid is polarized, using a 500 mm. tube, and the result obtained as % on the bagasse by reading from a table. P. insists that the following points are essential in order to obtain the exact av. amt. of sugar in bagasse: (1) A sampling of the bagasse the entire depth of the layer from the center as well as from both sides; (2) mixing sample and passing 2 to 3 kg. through a cutting machine to obtain a fairly fine and even material; (3) proper mixing of the divided sample and the detn. of the sugar in it by a method which is simple and of sufficient exactness; (4) the testing of the sucrose content of the bagasse as often as possible (at least every $\frac{1}{2}$ hr.), thus obtaining an exactly av. result at the end of the shift. P. believes that the app. and method proposed by Deerr (*C. A.* 9, 2323) may give every satisfaction, but not as quick results as obtained with the Norris app. A. GROSS.

The decomposition of reducing sugar under the conditions existing in cane sugar manufacture. T. VAN DER LINDEN. *Arch. Suikerind.* 22, 653-85 (1915).—An artificial juice was made of 225 g. sucrose, 50 g. of a soln. of 77% invert sugar, 5 g. Ca acetate, and enough CaCl_2 to give 0.3-0.4% Cl in the final soln. The whole was then dild. to 1.5 l. The CaCl_2 was added to furnish a point of reference, on the assumption that it would be unchanged and not affect the reactions. All results were compared, not as detd., but after calcg. to 100 Cl. Preliminary expts. showed that though there was some inversion on evapg., the (invert equiv. of sucrose) + (invert found) was constant. The above juice was subjected to clarification and evapn. by (1) defecation, (2) sulfuring directly after CaO at ordinary temp., (3) sulfuring at ordinary temp. 20 min. after CaO, (4) sulfuring and liming simultaneously at 60°, (5) the same at 80°, (6) single, and (7) double carbonation. These last 2 were carried out (a) by the "old" method, (b) De Haan's method (alkalinity controlled at about 0.25° CaO by gradual addition of CaO during carbonation), (c) old method followed by SO_2 , and (d) De Haan's method followed by SO_2 . Each method was tested as above, and also with juice in which half the Ca acetate was replaced by K acetate. All results are given in full. Owing to the small amt. of Cl in the solns., errors in its detn. were multiplied in the calcns., so that the final results (expressed as invert decomposed in % of invert introduced) are subject to an uncertainty of 1-2% on the thin juice, and 5% on the thick. No loss of invert could be detd. in method (1). No method of sulfuring gave a loss from raw juice to thin juice, and only (2) and (4) showed a loss from thin to thick. The losses were less with K acetate than with Ca acetate. In carbonation the greatest losses were from raw juice to thin juice, while from thin to thick there was no loss. Sulfuring after carbonation had no effect, and all tests by the old method gave greater

losses than by De Haan's method. The total losses from raw juice to thick juice (uncertain by $\pm 6-7\%$) were:

Method.	1.	2.	3.	4.	5.	6a.	6a.	6b.	6d.	7a.	7c.	7b.	7d.
Ca acetate.....	2%	16	6	11	4	10	10	5	..	11	..	12	..
K acetate.....	—1	3	6	3	13	9	8	7	3	12	13	5	6

In all cases a decompn. of invert was accompanied by an increase in polarization, showing that fructose was more rapidly decompd. than glucose. Since fructose is present only in small amts. in cane, these figures for invert should be higher than in practice. Figures from practice for 1912 are: loss of invert in % of invert introduced, in defecation, 12.3% (av. of 23); sulfitation, 15.0 (av. of 26); and carbonation, 21.5 (av. of 10). The difference is ascribed to more accurate control in the lab. tests, and to the presence in factory juices of organic acids which form Ca salts hydrolyzing to alk. reaction.

W. L. BADGER.

Deterioration of sugar and filtration of the juice. R. L. Y. GUIJARRO. *Louisiana Planter* 54, No. 4, 61-2(1915).—G. recommends the filtration of the raw juice to remove bagacillo and other suspended matter which carry organisms that infect the juice and cause subsequent deterioration of the sugar.

A. GROSS.

Deterioration of cut canes. W. E. CROSS AND J. A. BELLÉ. *Intern. Sugar J.* 17, 218-24(1915).—The deterioration is shown to be due to enzymic action. The enzyme is probably invertase which is known to be present in immature cane tops (Browne, La. Expt. Sta., *Bull.* 91, 17 pp.) The presence of an enzyme may be shown by macerating the tops and adding some of the juice to a pure sugar soln. of known strength kept sterile by a little CHCl_3 and toluene. In a few hrs. considerable inversion will take place. It was further shown that the enzyme is present in greater proportion in the stored cut canes than in the freshly cut canes. The enzymic action is thought to be connected with the prepn. of the plant for germination. When germination takes place the sucrose is used up but is first changed to invert sugar. It is noted that those varieties of cane which germinate most rapidly deteriorate fastest. The most successful methods for preventing deterioration are: (1) Cane stored in a heap, covered with trash, and kept wet by drenching. (2) Cane stored in a heap and covered with trash. (3) Cane stored in a shady place. Method (1) has been successfully employed in Java and the West Indies. Method (2) is best adapted for work in the field. Obviously, the better way is to treat all of the cane immediately after cutting.

H. R. SMITH.

The fermentation of table sirups and means for its prevention. WM. L. OWEN. *Sugar* 17, No. 8, 29-31(1915).—The species of yeast causing the formation of gas during fermentation resulting in a swelling of the tops and sides of the cans containing the sirup was found to be so resistant to high temps. that exposure for 15 min. at 90° was necessary for its destruction. In most of the cases the deterioration of the product was due primarily to a gaseous and not to an acid fermentation. Most of the infection is due to uncleanness.

A. GROSS.

Molasses. A. MCGILL. Inland Revenue Dept., Ottawa, Canada, *Bull.* 312.—The report contains the results of detns. of moisture, ash, reducing sugars, sucrose and organic non-sugars on 140 samples of molasses collected throughout Canada. The solids vary from 70 to 80%, the reducing sugars from 10 to 37%, cane sugar from 25 to 54%, and ash from 1 to 9%. Seventy-five samples contain less than 40% sucrose and are considered as doubtfully suited for human food under the name molasses; 38 samples contain more than 5% of ash and would undoubtedly be more correctly offered as *black-strap* than as molasses. No legal standards exist in Canada.

A. H. BRYAN.

The by-products of the cane sugar industry. II. Cane Wax. W. E. CROSS. *Intern. Sugar J.* 17, 311-3(1915); *Sugar* 17, No. 8, 37-8(1915); cf. *C. A.* 9, 2463.—The cane wax obtained by C. from filter press cakes in the province of Tucuman (Argentina) was of a greenish color (due to the presence of chlorophyll) and was much softer than the true cane wax, m. 60-70°. It consisted of a saponifiable and an unsaponifiable portion, the latter being true cane wax and the former consisting of fats, oils, etc., occurring in the cane. By fractional crystn. from benzine (the method recommended by Wynberg), it was possible to sep. the cane wax from the other constituents. The wax so obtained had the m. p. 78-80° and after purification and recrystn. it m. 81-83°. In its hardness and other properties it also corresponded with the true cane wax. As the extn. of the wax from filter press cakes by volatile solvents would not be profitable from an industrial point of view, C. carried out some expts. with the various products sepd. from raw juice by means of a large juice centrifugal, in which suspended substances of different sp. gr. appeared to collect in sep. chambers. It was found that one product contained pure wax to the extent of over 50%. The wax could be easily obtained by extn. with alc. and appeared to be almost entirely free from the fatty contamination found in the crude wax from filter press cake. After one crystn. a pure hard wax of a m. p. 82° was obtained. With the perfection and adoption of juice centrifugals C. expects the extn. of cane wax to become a com. success. A. GROSS.

Performance tests of sugar-house heating and evaporating apparatus. E. W. KERR, J. F. GUNTHER AND W. A. ROLSTON. La. Agr. Expt. Sta., *Bull.* 149; *Mel. Chem. Eng.* 13, 485-92, 506-7(1915).—There are two general types of vacuum pans, calandria and coil. The coil pans include single, double, triple, and quadruple coils with one or many manifolds. Among the calandria patterns are the straight, horizontal tube sheets, the inclined tube sheets, and the Express pan with inclined tubes as well as tube sheets. The heat transmission in vacuum pans is greater than in evaporators, the temp. fall with 60 lbs. steam at 26 in. mercury being 182°. Where exhaust steam at 10 lbs. gage is used, as is often the case with the calandria type, the temp. fall will be about 100°. The greater the hydrostatic head the greater will be the pressure, and the boiling temp. will be considerably higher than that indicated by the vacuum gage. For this reason it is better to employ pans with relatively large diam. and small height. The higher the density and the lower the purity of the boiling liquid the greater will be the rise in b. p. above the theoretical. The velocity of circulation of the boiling mass greatly affects the heat transmission. In coil pans the space between coils in horizontal directions affects the circulation. Also in placing the coils one above another the space from top to bottom should be as straight as possible in order to place the least possible resistance to the upward flow of the liquid. The supports for the coils should be placed with care. In some coil pans a circulation is maintained mechanically by a revolving screw in the vertical axis of the pan. In the calandria pans a more definite path for the circulation is produced. The Express pan is provided with a false shell, as a result of which the liquid rises in the center and flows down between the shells in well defined paths. A rapid flow of steam through the heating tubes increases the coeff. of heat transmission but no steam should be allowed to flow from the end of the coils. The water of condensation must be promptly removed in order to maintain high efficiency. In calandria pans this may be done by the use of traps or automatic receiver pumps. Coil pans are fitted with automatic receiver pumps, single traps, traps for each coil, or adjustable check valves. The condensed water is handled by the "closed" or the "open" system. In the former the water is returned to the boiler without releasing the pressure. In the "open" system the water is pumped to a storage tank from which it is conducted to the boiler. Diagrams representing each type are given and explained. In coil pans the length and diam. of the coil and its inclination

to the horizontal affect the draining qualities. The carrying-away capacity is proportional to the diam. and the condensing power is proportional to the length, so the ratio of length to diam. is important. This should not exceed 200. The heat efficiency depends entirely on the radiation. For this reason fast boiling is much to be desired. A series of tests on 23 pans of all types demonstrated that the coeff. of heat transmission is 40% greater in the Express pan than in the av. coil pan. The rise in temp. of boiling due to hydrostatic head, density, and purity was also less in the Express pan. This greater efficiency of the Express pan is undoubtedly due to the more rapid circulation of the boiling mass, and to the more efficient removal of the condensation. Efficiency tests involving steam consumption and heat balance showed no difference in economy for coil and calandria pans.

H. R. SMITH,

Results of experiments with stoking with bagasse. H. C. PRINSEN-GEERLIGS. *Louisiana Planter* 54, No. 5, 76-7(1915).—The furnace for the combustion of moist bagasse should be constructed so that the incompletely burned gases formed by destructive distn. in the higher strata of the fuel on the grate can be burned in a secondary current of air. This may be done by an inclination of the current of the gases which are forced back over the fire before being allowed to reach the boilers. Further, it is evident that the finer and more moist the bagasse is, the thinner must be the layer on the grate, and the finer the bagasse is, the slower must be the draught in order to prevent mechanical loss.

A. GROSS.

Estimation of raffinose (HUDSON) 7.

U. S., 1,148,453, July 27. A. S. HOYT. Laundry starch is prepared from wheat or other glutinous raw material by removing the gluten, sepg. the remaining albuminous material from the starch by centrifuging with a large vol. of H_2O , then removing all the H_2O present, except that required to prevent the starch from burning, cooking the starch to a jelly and drying the jelly.

U. S., 1,148,454, July 27. A. S. HOYT. Starch is prepared as in the preceding pat. and reduced to a powder which forms an opalescent jelly on the addition of H_2O .

U. S., 1,149,216, Aug. 10. C. S. PERKINS. Starch mixture for use in laundry work; formed of starch 6, NaCl 0.5, borax 0.5, and wax 5 parts.

U. S., 1,150,194, Aug. 17. W. D. HORNE. Removing iron compounds from sugar solutions. Na_2HPO_4 and H_2S or $(NH_4)_2S$ are added to the soln. A creamy aq. mixt. of $Al(OH)_3$ or clay may also be added to facilitate pptn. of the Fe.

29. LEATHER AND GLUE.

LLOYD BALDERSTON.

Influence of method of subdivision of leather on results of analysis. R. LAUFFMANN. *Ledertechn. Rundschau*, May 22, 161-4(1915).—The only notable differences between ground and cut samples are in water-sol. matter (higher in ground sample) and in the Proctor-Hirst test for sulfite cellulose ext. (stronger in cut sample, cf. C. A. 9, 2161). Small differences in % of SO_3 and of fat, L. attributes to influence of particles of iron from the mill in the ground sample.

L. B.

Filter papers. F. H. SMALL. *J. Am. Leather Chem. Assoc.* 10, 282-91(1915).—Report of collaborative work comparing S. & S. 590 with Munkell's 1 F in filtering

tannin solns. No difference was found and it was shown that variations in the wt. of filter paper did not affect the results. L. B.

Osage orange as a substitute for fustic. F. W. KRESSMANN. *J. Am. Leather Chem. Assoc.* 10, 347-51(1915).—Expts. on various fibers and on chrome-tanned calf leather show that osage orange from Texas and Oklahoma may be substituted for fustic in dyeing, giving practically identical results. The dyeing principles are chemically the same in the two woods, the amt. contained in osage orange being slightly less. Northern grown osage orange does not give good results. The supply in Texas and Oklahoma is large, and it can be placed on the market at a price which will enable it to compete with fustic. L. B.

Extraction of valonia. L. BALDERSTON. *J. Am. Leather Chem. Assoc.* 10, 417-20 (1915).—Time is an important factor. Spent valonia which had been leached for 6 days, yielding in the liquors as much tannin as was shown by the official analysis to be present, continued to yield tannin for 48 hrs. longer when extd. in a Teas extractor. A new sample placed in a Teas extractor yielded tannin for 72 hrs., and during 11 additional 24-hr. periods yielded amts. of extraction material ranging from 1.4% to 0.3%, the tannin-free extract containing a yellow dye similar to quercitrin. A quantity of this ext. was evapd. to dryness, the residue being subjected to dry distn. and the distillate treated with Br. A yellow ppt. formed; it is apparently the same as that obtained by Bennett's expt. on valonia ext. (*C. A.* 8, 3871; 9, 977). L. B.

Color due to copper extractors. T. G. GREAVES. *J. Am. Leather Chem. Assoc.* 10, 414-7(1915).—Chestnut wood was extd. in copper and glass extractors, and exts. prepared from the liquors were tested with the Schmidt and Haensch colorimeter as modified by Kerr (*C. A.* 9, 534). In every case the color of the copper extd. sample was darker. L. B.

Chemical control of the beamhouse. J. HELFRICH. *J. Am. Leather Chem. Assoc.* 10, 396-408(1915).—Results of several practical tests with packs of horse-hides and calf skins are given. Dissolved hide substance in the soaks was detd. by Stiasny's method. When skins are unhaired with Na_2S , they are afterward drummed with NaHCO_3 to neutralize the alkali remaining in the skins. After drumming for an hour the amt. of NaHCO_3 in soln. is detd., an excess showing the operation to be complete. Available lime in the lime liquors is detd. by titration with 0.1 *N* H_2SO_4 , first with phenolphthalein indicator and then with methyl red. The difference between the 2 readings may be assumed to indicate $\frac{1}{2}$ of the Na_2S present in the lime liquor. Total alkali is detd. by the first titration. Na_2S in lime liquors is detd. either by treating with CdCl_2 and CH_3COOH , dissolving the washed ppt. in HCl and titrating with 0.1 *N* I , or by titrating the filtered liquor with 0.1 *N* ZnSO_4 , using Pb acetate or Na nitroprusside as outside indicator. Hide substance in lime liquors is detd. by Stiasny's method. Bate liquors are examd. for $\text{Ca}(\text{OH})_2$ and pickle liquors for free acid. L. B.

U. S., 1,149,298, Aug. 10. W. S. SHAW. **Tanning hides.** The hides are immersed in a tanning soln. in a sufficiently high vacuum that the soln. boils at 24° or below, and the green hides are boiled in this soln., the temp. being so low that they are not injured; as the tanning progresses, the temp. and pressure are gradually increased.

U. S., 1,149,645, Aug. 10. C. W. GROSS. **Composition for toughening leather,** composed of rosin $\frac{1}{2}$ pint, linseed oil 1 pint, shellac $\frac{1}{2}$ pint, mutton tallow 1 pint, and gasoline 1 pint.

U. S., 1,150,047, Aug. 17. A. McLENNAN. Waterproofing leather. See Brit., 21,081 (C. A. 8, 1033).

Brit., 8,837, Apr. 7, 1914. J. H. YOCUM. Preserving fresh hides prior to tanning by salting them with a mixt. of a neutral salt of Na and a small % of normal sulfite of Na or a similar base, such as K or NH_4 . The mixt. is sprinkled on the hides in the usual manner and has the effect of eliminating salt stains in the tanned product. The preferred mixt. contains 97% of NaCl and 3% of Na_2SO_3 . The chloride may, however, be replaced by sulfate or other neutral salts of Na.

Brit., 8,877, Apr. 8, 1914. O. RÖHM. In leather manufacture, sulfonated oils or fats free from soap are used as a substitute for yolks of eggs in making glacé or kid leather or for treating vegetable-tanned leather before, during, or after tanning. Volatile substances sol. in oil, such as toluene or ethyl acetate, may be added. In tawing, the depilated hides may be treated with the sulfonated oils separately from the alum bath.

CHEMICAL ABSTRACTS

Vol. 9.

OCTOBER 20, 1915.

No. 20.

I. APPARATUS.

L. C. JONES.

Simple automatic-zero buret. A. T. MERTES. *J. Ind. Eng. Chem.* 7, 786-7 (1915).—The excess overflow discharges directly into the main reservoir. I. M.

Two convenient forms of receiver for fractional distillations under diminished pressure. M. T. BOGERT. *J. Ind. Eng. Chem.* 7, 785-6 (1915).—An app. has been devised by which any number of fractions of large vol. can be collected separately without interrupting the vacuum. ISADOR MILLER.

Desiccator with an improved cover. ANON. *Z. angew. Chem.* 28, I, 324 (1915).—The cover described is provided with a vertical ring, which fits inside the body of the desiccator. The advantage claimed is that the desiccator may be easily carried from place to place without danger of the top slipping off. H. R. GUNDLACH.

A simple method of converting the Duboscq colorimeter into a nephelometer. W. R. BLOOR. Harvard Med. School. *J. Biol. Chem.* 22, 145-9 (1915).—The Duboscq colorimeter with movable cups can readily be transformed into a nephelometer by replacing the glass plate carrying the prisms with one fitted to receive 2 glass tubes. The colorimeter cups are replaced by 2 metal jackets. In the old-style instrument, with movable prisms, the change is more difficult. The nephelometer and the source of light, a 50-watt tungsten lamp, are enclosed in a light-tight box. I. GREENWALD.

Notes on micro-gravimetric analysis. J. DONAB. *Monatsh.* 26, 381-90 (1915); cf. C. A. 7, 2169.—Description of D.'s recent modifications in app. for micro-gravimetric analysis, such as filtering funnel, pptn. tubes, desiccator, drying oven, etc. E. W. BOUGHTON.

A reversion micrometer. O. LUBARSCHE. Berlin. *Z. physik. chem. Unterr.* 28, 198-200 (1915).—The app. consists of a graduated measuring buret and leveling tube adjustably clamped on a stand and connected with a strong rubber tube. The top of the buret is inclined at about 45° and a ground joint carries a receiver consisting of a short glass tube bent at the middle at 120°, the outer end closed and a separatory funnel of 6 cc. capacity fused in at the upper side of the bend. The substance is weighed into the receiver which is slipped into the ground joint, the H₂SO₄ run in from the funnel and let stand a few min. The receiver is then turned 180° so that the H₂SO₄ flows with the substance into contact with the Hg in the buret, causing the reaction to take place. Detailed directions for operating are given. J. H. MOORE.

A Kjeldahl distillation apparatus. J. M. PICKEL. *J. Ind. Eng. Chem.* 7, 787-9 (1915).—P. describes a simplified app. for which he claims many advantages. I. M.

G. Preuss's new apparatus for the determination of carbon. ANON. *Chem. Ztg.* 39, 652 (1915).—An ordinary evolution app. with a soda-lime tube fitted into the acid funnel to purify aspirated air. J. H. MOORE.

Continuous chlorine generator. A. VOSMAER. *Chem. Weekblad* 12, 576-7 (1915); cf. *Z. anal. Chem.* 27, 638 (1888).—The app. consists of a Wolff bottle, one opening of which is provided with a delivery tube for the Cl gas, and the other for the

admission of the acid supply tube, the latter reaching to the bottom of the bottle. A piece of glass marble is placed on the bottom, and upon this is placed the pyrolusite in lumps of 5 mm. diam. The HCl reservoir is placed 5 cm. above the generator flask. The HCl tube is provided with a 3-way stopcock, connecting in one position the reservoir with the generator, and in the other the generator with the outside air. In the latter position the Cl₂ will pass out of the bottle, thus interrupting the process. During the evolution of gas the app. is warmed to 50°.

P. VAN DER MEULEN.

A new filter press process. F. ULZEN. *Z. angew. Chem.* 28, I, 308(1915).—The new filter press cake makes use of the principle of electroosmosis in the filtering process, by which a rapid filtration of liquids containing very fine particles may be made without clogging the filter cloth. In general, when a current is passed through a liquid containing a solid phase, the solid phase, according to its elec. character, will either wander in or against the direction of the current, and will have the tendency to attach itself in a more or less dry state to one of the electrodes. In other cases the solid phase does not move in either direction of the current, but the particles settle to the bottom, while the liquid has the tendency to flow away from the electrodes. The design of the filter press is similar to the usual form; it consists of a number of chambers in which the filtration takes place. The difference is that electrodes are placed in each of the chambers, by which means the current is passed through the liquid. The chambers are filled with the liquid to be filtered, the current passed through and the solid phase then either wanders to one of the electrodes or falls to the bottom, leaving the liquid free to pass through the filter-cloth. This prevents a rapid clogging of the cloth and removes the necessity of high pressures to insure rapid filtration. This press efficiently separates the finest particles from liquids, and can be used for highly plastic clays, ceramic mixtures of plastic character, anhydrous colors, colloidal dyestuffs, barium sulfate, etc.

Brit., 9,019, Apr. 22, 1914. W. A. STEDMAN. *The lower edges of the cloth of a filter leaf hang loosely down below the bottom frame member to*

form flaps which act as valves, closing under the vacuum but enabling the liquid used for dislodging the cakes to flow readily from inside outwards if the pressure inside exceeds that outside.

Brit., 9,221, Apr. 22, 1914. C. BUTTERS. In a filter for mixts., such as ore slimes, requiring aeration during filtration, the liquor is passed in a shallow stream over horizontal filtering surfaces in such a manner that the incoming stream of liquor produces a continuous circulation of the unsettled solid matter while the filtration proceeds.

172
The filtering surfaces have suction chambers below and are mounted so as to be tiltable for controlling the thickness of the cake and ultimately for discharging the cake by being placed approx. vertical. ~~Cylinder or other form~~ may be passed through the cake on the filtering surfaces.

Brit., 10,071, Apr. 23, 1914. R. NÜBLING and A. KRAUSS. Gas retorts and sewage distilling retorts in the same setting, with flues so arranged that the retorts are heated by the waste gases from the chamber surrounding the gas retorts. The gases generated in the 2 sets of retorts may be mixed. The retorts may be horizontal, inclined, or vertical.

Brit., 10,351, Apr. 27, 1914. DU PONT DE NEMOURS POWDER CO. App. for recovering volatile solvents used, e. g., for coating paper, textile fabrics, etc., by means of gas currents circulating by convection, comprises a drying chamber, into which the goods are placed or passed, adjacent to its lower wall; fitted adjacent to the upper wall of the app. are heating coils or other source of radiant heat, the distance between the goods and the heating means being relatively small. The gas current is circulated by cooling and heating means, between which is situated a condenser for the recovery of the solvent. Means for reducing the dimensions of the app. without interfering with the efficiency of the gas circulation are provided. E. g., an upwardly directed passage may be formed at the exit end of the drying chamber, or the cooling coils and the condenser coils are superposed.

Brit., 10,374, Apr. 27, 1914. G. ORNSTEIN. In apparatus for treating flowing liquid with a constant proportion of gas, e. g., for treating sewage with a sterilizing gas such as Cl, the gas is supplied under pressure and passed through a throttling orifice of known section, and a pressure-regulating device is arranged in front of the orifice and controlled by the pressure difference at different points of the current, which may flow through a Venturi tube.

Brit., 10,394, Apr. 27, 1914. H. A. A. J. LELARGE. A filter for removing impurities from gases and vapors, e. g., oil from exhaust gases or steam, or tar which is to be condensed, comprises a series of metallic spirals arranged in layers, the axes of those of adjacent layers being at right angles, and the spirals coated with a viscous liquid. The whole is arranged in an air-tight casing.

Brit., 10,400, Apr. 27, 1914. SCHÖLLER & CO. and M. ALBRACHT. In app. for detecting injurious gases in mines and other places, and working on the diffusion principle, the indicating U-tube is of such small section and the liquid is of such small mass that it can only be moved out of position very slowly by shaking; and the indicating tube is placed in the path of the rays of light from the miner's lamp on which the device is carried, and is arranged so that an increase in pressure of the liquid in the diffusion chamber causes a bubbling of gas through the liquid.

Brit., 10,522, Apr. 28, 1914. R. C. W. LYONS. A pulverizing machine for reducing specimens for assaying and other purposes, is constructed so that there are no ledges or projections inside the casing on which the ground material can settle.

Ger., 283,599, Nov. 28, 1913. G. BUNZOW. A fluorescent screen for X-ray rays, the fluorescent mass is applied to a base with mirror surface.

Ger., 283,704, Oct. 17, 1912. V. FRIEDL. Rotary condenser for gas.

Ital., 140,597, Mar. 25, 1914. CENTRALSTELLE FÜR WISSENSCHAFTLICH-TECHNISCHE UNTERSUCHUNGEN. App. for effecting gas reactions, in which H² or a mixt. containing H participates. Two vessels are provided, an inner vessel, chemically resistant and impermeable to H², and an outer vessel able to withstand pressure. The space between the vessels may be filled with an inert gas which may be maintained, by a suitable device, at the same pressure as that prevailing in the inner vessel.

2. GENERAL AND PHYSICAL CHEMISTRY.

WILLIAM D. HARKINS.

Assistants: E. B. MILLARD and A. B. CARTER.

Invariant, monovariant, and divariant equilibria. I. F. A. H. SCHREINEMAKERS. *Proc. Akad. Wetenschappen* 18, 116-26(1915).—A discussion of the position of the curves and regions representing the mono- and divariant equil. which may proceed from an invariant point in a P - T diagram. GEORGE W. MOREY.

Possible cause of the doubling of the Raoult effect in dilute solutions of electrolytes. RUD. KOHL. *Sitzb. K. Akad. Wiss. Wien*, 123, IIA, 26 pp.(1915); through *Chem. Zentr.* 1915, I, 1147.—K. has calcd. the internal energy of a substance from its equation of state, and from this the entropy and free energy in an explicit form. This equation allows the equil. condition to be calcd. from the thermodynamic potential, and then the expression for the Raoult effect (lowering of vapor pressure, f. p., rise of b. p., etc.) in a simple manner. To explain the anomaly of this effect in dil. solns. of strong electrolytes the theory of dissociation into ions is not required, and may be replaced by another equation of state, such as that of Eisenmann (*C. A.* 7, 303). The doubling of the effect is caused by the characteristic electromagnetic vibrations within the mol. E. B. MILLARD.

Experiments on supersaturated solutions. M. JONES AND J. R. PARTINGTON. *J. Chem. Soc.* 107, 1019-25(1915); cf. W. J. Jones, *C. A.* 7, 3057; 9, 876.—The existence of supersatd. solns. which deposit solid when the temp. is raised was established for $\text{Ca}(\text{OAc})_2$ and Ca butyrate, and (indirectly) for CaSO_4 . The theory, as applied to CaSO_4 , may be stated $RT/M \log_e S_r/S_\infty = 2\sigma/\rho r$, where M is the mol. wt. of the solute, σ the energy per unit area of the surface of sepn. of solid and soln., ρ the density of the liquid, and S_r and S_∞ the concns. of solute when spherical particles of radius r and plane surfaces of the solid, resp., are in equil. with the soln. If concn. is plotted against temp., a max. in solubility at about 40° is found for particles varying in size from $r = 0.5 \mu$ to $r = 50 \mu$. The influence of size has practically disappeared with radii greater than 50μ . Solubility was detd. from sp. cond. of solns. of pure gypsum powders. The existence of equilibria between finely divided gypsum and solns. in contact with it, with concns. different from those in normally satd. solns., was established by approaching the equilibria from both sides (supersatn. and undersatd. soln. + solid) and detg. the concn. from cond. The solubility agreed with that calcd. from the theory of Gibbs, according to which the solubility of a powder is greater than that of planes of the same substance by an amt. which may be calcd. from the energy located at the surface of discontinuity between solute and soln. E. B. MILLARD.

Molecular condition of mixed liquids. II. Application of Traube's atomic volume method to binary mixtures. W. R. G. ATKINS AND K. SHIPWAY. *J. Chem. Soc.* 107, 1117-21(1915); cf. *C. A.* 7, 3694.—The earlier results pointing to the existence of hydrates of the simple aliphatic alcs. should be attributed to the mixt. of highly associated liquids, for the mean of the association factors of H_2O and the alcs. is slightly above 2 and is lowered to almost exactly 2 by diln. with an equimol. wt. of another liquid. Owing to an error in calcn., in Part I, this conclusion was thought to be negatived by the values found. From detns. of the mol. vol. of each liquid in a binary equimol. mixt. in 46 cases it was concluded that in cases in which Traube's method indicates the absence of a compd., the result may be safely accepted, but the cases which apparently show the existence of a compd. are in need of further consideration, for in many cases the values found are due to the av. of the association factors of the mixed liquids having a value in the neighborhood of 2. E. B. MILLARD.

Absorption spectra of mono-substituted benzene compounds, and the benzene substitution law. E. C. C. BALY AND F. G. TRYHORN. *J. Chem. Soc.* 107, 1058-70 (1915); cf. *ibid* 87, 1332 (1905).—The chem. reactivity of a mol. depends on the condition in which its force field exists. If the field be entirely closed, the reactivity will be vanishingly small, and it will be necessary that the field be opened before any reactivity can be developed. This opening-up takes place in stages, one or more of which may be produced by means of a suitable solvent. The marked difference between *p*-xylene and its isomerides is shown in 3 ways: the amt. of light absorbed by the same mol. concn. is enormously greater, the band is more subdivided, and the persistence is much greater. When the 2 substituent groups are of the electropositive type, the force field of the para-isomeride is the least closed of the 3. Then when any mono-substituted C_6H_5 compd. shows a pronounced absorption band, it must give a para-disubstitution product, or at least that product will greatly predominate. It was also shown that meta-substitution renders the force field of a compd. relatively closed, in spite of the fact that the same substituting groups do not give a closed field when in other positions. The absorption curves of 22 mono-substituted C_6H_5 derivs. are shown, in all but 3 of which (benzyl ethyl ether, Et phenylacetate and benzonitrile) the absorption curves agree with the reductions from the force-field theory. E. B. MILLARD.

Relation between infra-red and ultraviolet absorption and the variation in absorption with concentration. E. C. C. BALY AND F. G. TRYHORN. *J. Chem. Soc.* 107, 1121-32 (1915); cf. preceding abstr.—The effect of the nature of the solvent and concn. has been investigated for several organic substances in a variety of solvents. On the addition of a solvent to a substance exhibiting selective absorption, the absorption band at first shifts toward the red until a minimum value of the central frequency is obtained, the concn. at which this occurs depending on the relation between the affinities of solvent and solute. Further dilution causes a progressive shift of the center of the band toward the shorter wave lengths, until at great diln. a const. max. frequency is reached. This max. frequency is the same as that exhibited by the absorbing substance in the state of vapor. Further confirmation has been obtained that the center frequencies of all absorption bands in the visible and ultraviolet regions are whole multiples of a fundamental frequency in the short-wave infra-red. The shift of the absorption band on diln. is due to the shift of this fundamental frequency caused by the solvent. There is also, accompanying these changes, an increase in the absorptive power up to a max. If K be the max. absorptive power, and k that at any concn., then $k/K = 1 - e^{-aV^{1/n}}$ where a is a const., V the vol., in liters, contg. 1 g. mol. of the solute, and n a number depending on the number of entities into which the mols. are reversibly resolved by the solvent. E. B. MILLARD.

The decolorization of fuchsin solutions by amorphous carbon. A. B. D. FORTUYN. *Proc. Akad. Wetenschappen* 17, 1322-5 (1915).—A 0.01% soln. of Neufuchsin on being decolorized with pure amorphous C and filtered resumes its color after the lapse of some time, the phenomenon being best observed when not enough C is added completely to decolorize the soln. The addition of AcOH to the soln. greatly accelerates the action. Crystal violet does not act in this manner. F. suggests a reconstruction of dye from uncolored dye-cations and Cl ions. B. RAYMUND.

Influence of temperature on the internal pressure of a gas. A. LÉDUC. *Compt. rend.* 161, 97-100 (1915); cf. *C. A.* 5, 3642.—Further calcns. on SO_2 extended to 1000°. The "internal pressure" at first falls rapidly with increasing temp., then more slowly. From the curve showing this pressure against temp. it appears that the internal pressure approaches a finite limit as T increases indefinitely, and does not approach zero as demanded by the equation of Clausius and Sarrau. E. B. MILLARD.

The probability of ionization and radiation of gas molecules due to collisions with electrons. K. F. NESTORCH. Petrograd. *Phil. Mag.* 30, 244-8(1915).—If one or the other takes place on inelastic collision in electropositive gases, the probability for ionization is 0.4 in argon and 0.9 in helium. G. L. WENDT.

Experimental determination of the law of reflexion of gas molecules. R. W. WOOD. Johns Hopkins Univ. *Phil. Mag.* 30, 300-4(1915).—A "one-dimensional gas" was produced by gently distg. Hg from an inclined neck through a sharp angle into a highly exhausted vertical tube immersed in liquid air. Laterally moving vapor particles rapidly condensed on the walls, leaving only the vertical stream. After passing through a narrow constriction the beam is wholly one-dimensional and even temp. and pressure are directional. Plates of polished glass and of mica placed obliquely in the stream and kept warmed reflect the molecules, but reflection is independent of the angle of incidence. Photographs confirm the usual assumption that the number of mols. reflected in any direction is proportional to the cosine of the angle between that direction and the normal to the surface. But when the angle is greater than 80° there is no reflection whatever. This is attributed to surface irregularities of molecular size. A preliminary expt. showed the gas stream to be elec. non-conducting.

G. L. WENDT.

Dynamics of isomeric change. Keto-enol transformation of cyanoacetate and its derivatives. H. M. DAWSON, R. SUGDEN AND A. TAYLOR. *J. Chem. Soc.* 107, 1030-8(1915); cf. *C. A.* 8, 1374.—The reaction between $\text{CNCH}_2\text{CO}_2\text{H}$ and the halogens proceeds too rapidly to permit of measurements at 0° , but the velocity was so much less when the Na salt was used that the reaction could be followed from the change in cond. produced by the HX formed. With Br the reaction proceeds to completion, but in the case of I a condition of equil. is reached which depends on the initial concn. of Na cyanoacetate and of I. The halogen substitution is auto-catalytic in character and appears to be preceded by the conversion of the inactive keto- into the active enol-form. It is probable that the Na derivs. of cyanoacetic esters are enolic compds. corresponding with the formula $\text{CN}:\text{CH}:\text{C}(\text{ONa})\text{OEt}$. From expts. in which a relatively large proportion of cyanoacetate was used, it appeared that the rate of disappearance of halogen from the soln. increased with the concn. of the salt but was independent of the concn. of the halogen. Further expts. were made in which solns. contg. 0.1 mol. of Na cyanoacetate per l. were mixed with relatively small and varying quantities of halogen at 0° , and samples added, after measured intervals of time, to KI solns., and the amt. of free halogen detd. by titrating the liberated I with $\text{Na}_2\text{S}_2\text{O}_3$. Here the velocity of the reaction was not entirely independent of the nature of the halogen (Br or I) as it should be if the rate of disappearance of halogen is solely detd. by the preliminary isomeric transformation. The velocity of the reaction is proportional at each moment to the quantity of halogen acid which has been set free in the substitution process. In consequence of the reaction between the Na cyanoacetate and the HX the auto-catalytic effect will be much smaller than that which would be produced by the unaltered halogen acid. E. B. MILLARD.

Allotropy and metastability of metals. ALFRED HOLT. *J. Soc. Chem. Ind.* 34, 693-7(1915).—The work of Cohen at Utrecht and of Smits at Amsterdam indicates that metals, as they are known, are not composed of similar molecules or molecular associations and that their properties are usually those of mixts. or solid solns. This, if true, is a matter of such great importance to the chemist, the physicist and the metallurgist, that it has seemed worth while to give a brief outline in English of the exptl. work that has been done and of the nature of the phenomena to which allotropy affords at least a plausible explanation. WILLIAM T. HALL.

The allotropy of sodium. L. ERNST COHEN. Utrecht. *Proc. Akad. Wetenschappen* 18, 91-8(1915); cf. *C. A.* 9, 987.—Careful measurements with Na in a dilatometer point to the conclusion that β -Na is monotropic in regard to the stable α -Na. No impurities could be detected in 10 g. of the Na, and it had a melting interval of from 97.22 to 97.51. The dilatometer had a vol. of 380 cc., diam. of bore 1.2 mm. The temp. of the thermostat used was controlled to 0.001°. G. W. MOREY.

Tension lines of the system phosphorus. IV. A. SMITS AND S. C. BOKHORST. Amsterdam. *Proc. Akad. Wetenschappen* 18, 106-16(1915).—New detns. of the vapor pressure line of liquid white P (cf. *C. A.* 8, 3146), with a dynamic isoteniscope similar to that previously used, but with a sensitive resistance thermometer immersed in the P, gave results which indicate, contrary to previous conclusions, that the v. p. lines of liquid white and liquid violet P are separate parts of the same curve. Both sets are well represented by the expression $T \ln p + 3.59 T \ln T = 37.62 T - 8257$, which gives the v. p. of liquid violet P from 169° (0.05 atm.) to 634° (56.8 atms.). Hence liquid white P is only supercooled liquid violet P; on this basis the P - T and P - X curves for the pseudo system are revized. GEORGE W. MOREY.

Crystal studies with the polarization microscope. P. METZNER. *Mikrokosmos* 1915-16, 86-90.—M. shows the application of the polarization microscope to the study of various crystals. Photomicrographs and methods of obtaining crystals of the following compds. are given: KNO_3 , Na_2CO_3 , CuSO_4 , NH_4NO_3 , $\text{C}_2\text{H}_4\text{O}_4$, NaNO_3 , and $\text{C}_6\text{H}_{12}\text{O}_6$. C. A. NOWAK.

The structure of the spinel group of crystals. W. H. BRAGG. Univ. Leeds. *Phil. Mag.* 30, 305-15(1915).—From the X-ray spectra and the molecular dimensions of a magnetite crystal B. concludes that it has fundamentally the same structure as the diamond, molecules of FeFe_2O_4 replacing the atoms of C. Intramolecularly, the O atoms lie all on 2 planes, while each trivalent Fe atom lies at the center of a regular octahedron of O atoms and each divalent at the center of a tetrahedron of O atoms. The (100) planes consist of Fe_2O_4 planes with the spacing 2.07 Å. interleaved with Fe planes. The (110) planes are Fe_2O_4 planes of spacing 2.94 Å. interleaved with FeO_2 planes. MgAl_2O_4 is exactly similar. G. L. WENDT.

Construction of the diamond with theoretical carbon atoms. ALBERT C. CREHORE. Columbia Univ. *Phil. Mag.* 30, 257-70(1915).—A discussion of the atomic forces involved. The length of the edge of the elementary tetrahedron is calcd. to be 2.528×10^{-8} cm. G. L. WENDT.

Phosphoric acid as mono- and di-basic acid. I. M. KOLTHOFF. Utrecht. *Chem. Weekblad* 12, 644-53(1915).—Qual. expts. showed that the reaction $\text{H}^+ + \text{HPO}_4^{2-} \rightleftharpoons \text{H}_2\text{PO}_4^-$ is endothermic; heating a soln. of Na_2HPO_4 which has been made neutral to phenolph. results in further hydrolysis, as shown by the indicator. Neutral salts have a marked effect on the color reaction of Na_2HPO_4 toward phenolph., and of NaH_2PO_4 toward dimethylaminoazobenzene; in the first case NaCl and NaNO_3 give a sharp color reaction on addition of a drop of acid. Potential measurements on mixts. of NaH_2PO_4 and Na_2HPO_4 with and without addition of NaCl soln. gave similar curves, the neutral salt soln. having a higher H^+ conc. H_2PO_4 can be titrated as a monobasic acid with dimethylaminoazobenzene, matching the color with a control soln. of NaH_2PO_4 , and it can be titrated as a dibasic acid with phenolphthalein, after addition of an equal vol. of dil. NaCl soln. GEORGE W. MOREY.

Different chemical activity of free and of combined water. H. C. JONES AND J. E. L. HOLMES. *Chem. News* 112, 73-4(1915).—The hydrolysis of HCO_2Me and AcOMe was studied in order to investigate the difference in chem. activity of free and combined water. The salts of Ca, Sr, Ba and Mg, which are strongly hydrated, in-

creased the reaction velocity to a greater extent than non-hydrated salts. The authors conclude that H_2O of hydration is more active than free H_2O . They assume that combined H_2O is more strongly ionized.

BERMAN.

Distribution coefficient and extraction velocity of some organic acids. J. PINNOW. *Z. anal. Chem.* 54, 321-45(1915).—For the detn. of extn. velocity, measured amts. of solns. of organic acids of known concn. were extd. in the Partheil-Rose app. (cf. *Ber.* 34, 3611(1901)), with ether which had been previously washed with NaOH and H_2O . The rate of application of the ether was such that the delivery of the ether from the condensing part of the app. was in drops too fast to be counted. The time of extn. was measured from the beginning of the rapid delivery of the ether from the condenser. Concns. of acid were detd. by titration, after the addition of 5 cc. of boiled water, with 0.5 N NaOH, using phenolph. indicator. In the case of AcOH water was added to lessen the volatility of the acid. Distribution coeffs. were detd. with ether purified as above. As com. lactic acid contains lactic anhydride, the latter was converted to lactic acid by treatment with concd. KOH and H_2SO_4 , the K_2SO_4 filtered off by suction and washed with ether; water was then added to prevent the reformation of lactic anhydride. For the other acids the prepns. of Kahlbaum were used. The extn. velocity coeff. was calcd. according to the equation $k = (1/t) \lg [a/(a - x)]$ where t = time in min., a = concn. at the beginning and $a - x$ the concn. at the end expressed in cc. of 0.5 N NaOH, $\lg$ = common or Briggs log. The distribution coeffs. between ether and water were detd. for the following named acids: acetic at 15°, succinic at 15, 20 and 25.5°, citric; tartaric, lactic and oxalic at 15°, and at 25-27.5°; also for oxalic after the addition of H_2SO_4 . The extn. velocity from aq. soln. of the acids named by varying vols. of ether with and without the presence of H_2SO_4 was detd. The extn. which follows essentially the formula for monomolecular reactions, is, within certain limits inversely proportional to the extg. vol., and approx. inversely proportional also to the distribution coeff. for 27°. The distribution coeff. of an acid at 27°, divided by 0.04, gives the time in min. for practically complete extn. Oxalic acid solns. should be treated with H_2SO_4 to the amt. of $1/6$ molar. A slight addition of H_2SO_4 to the other acids is recommended.

L. W. RIGGS.

Determination of the elementary electric charge from ferromagnetic properties and the magneton. JAKOB KUNZ. Univ. Ill. *Arch. sci. phys. nat.* 39, 488-93(1915); cf. *Phys. Rev.* 30, 359(1910).—Theoretical.

E. B. MILLARD.

Charged surface layers formed on the electrodes of vacuum tubes. K. T. COMPTON AND L. W. ROSS. *Phys. Rev.* 6, 207-12(1915).—The abnormal contact potentials produced on the electrodes by high potential discharges are due to and exist in insulating films such as grease or wax on the surfaces of the electrodes. Surface charges are produced on insulating films of small viscosity by convection currents in the film set up by the applied field, even though this field may be too small to produce a vacuum discharge. During a vacuum discharge a charged layer of gaseous ions is deposited on the surface of the insulating film. This charge is of a sign opposite to that of the potential of the electrode during discharge and is, therefore, opposite to that produced by convection currents. The apparent contact p. d. is the resultant of these effects, whose relative importance depends on the viscosity of the film and the nature of the discharge.

E. B. MILLARD.

Attempt to detect a change in the heat conductivity of a selenium crystal with a change in illumination. L. P. SIMS. *Phys. Rev.* 6, 213-8(1915).—No change was detected, possibly because the number of free electrons was so very small that even a 3-fold increase would be inappreciable, or possibly the no. of free electrons is not detd. solely by the state of light or dark, but largely by the elec. field intensity. The

source of light employed was able to change the elec. cond. 300% without producing a change as great as 5% in the heat conductivity. E. B. MILLARD.

Concentration cells built up from ammoniacal solutions of silver salts. A. REYCHLER. *Bull. soc. chim. belg.* 28, 222-7(1914).—R. considers the cell

Ag | NH₃ in excess, of uniform conc. | AgCl of concn. C | AgCl of smaller concn. c | Ag. In connection with the tendency toward equalization of the concn. of the Ag salt and consequent production of e. m. f., the passage of 96540 coulombs is associated with the transfer of $v/(u+v)$ moles of Ag salt from left to right (as above). The expression $96540 E = 2[v/(u+v)]RT \log (C/c)$ is then obtained by equating the 96540 E volt coulombs of elec. energy rendered available by the transfer of 1 g. atom of Ag and the max. osmotic work which corresponds to the isothermal dilatation of $v/(u+v)$ moles of AgCl from the concn. C to the concn. c (the Ag salt is considered totally dissociated at dilns. taken; hence the factor 2); if $2v/(u+v)$ be taken as unity, then $E = 0.058 \log C/c$. Values of E calcd. from this formula for various concns. C and c of both AgCl and AgNO₃, as well as NH₃, showed acceptable agreement with the experimentally detd. values observed by Bodländer and Pittig; this agreement indicates that the salts in question are quite simple and only contain 1 atom of Ag in the mol. R. next considers the cell

Ag | AgCl of uniform concn. | NH₃ of concn. C | NH₃ of smaller concn. c | Ag. Consideration of the possible concn. changes and assumption of the transfer of n mols. NH₃ by 1 atom Ag indicates that a possible complex Ag(NH₃) _{n} ...Cl does not participate in the production of the initial e. m. f., since it has initially the same concn. in both liquids; it is only necessary, therefore, to consider the concns. of free NH₃ and the max. work corresponding to the isothermal passage of n moles NH₃ from the concn. C to the concn. c . The expression $E = n \times 0.058 \log \{(\text{free NH}_3)/(\text{free NH}_3)_1\}$, is thus derived. Comparison of the exptl. values of Bodländer and Pittig with the calcd. values of E for various concns. of NH₃, as well as both AgCl and AgNO₃, showed that satisfactory agreement was obtained when $n = 2$. The Ag salts present in soln. in an excess of aq. NH₃ soln. are, therefore, to be represented by Ag(NH₃)₂...Cl and Ag(NH₃)₂...NO₃, resp. R. compares his theoretical deductions for these cells with the theory of Bodländer.

H. S. PAINE.

Metallic conduction. O. W. RICHARDSON. *London. Phil. Mag.* 30, 295-9 (1915).—Calcn. of the elec. moments of the doublets postulated by J. J. Thomson (*C. A.* 9, 2482) requires a distance between the charges of 2.92×10^{-8} cm. The number of free electrons per cc. is $6.2 \times 10^{22} d/d_1$, where d is the distance traveled by an electron in passing from one atom to another and d_1 is the distance between centers of neighboring atoms. The number of W atoms in a cc. is 6.16×10^{22} , so that if atoms are planetary systems and d is comparable to d_1 about half the specific heat of the substance is located in the free electrons; but if atoms have a definite boundary and electrons pass only where there is contact (d is zero) the electrons have no heat capacity. The former is regarded as more probable. G. L. WENDT.

The electron theory of metallic conduction. IV. G. H. LIVEN. Univ. Sheffield. *Phil. Mag.* 30, 287-95(1915).—A mathematical discussion of the law of distribution of velocities of free electrons, with especial calcn. of the mean time between two successive collisions of an electron. G. L. WENDT.

The effect of electric and magnetic fields on the emission lines of solids. C. E. MENDENHALL AND R. W. WOOD. Johns Hopkins Univ. *Phil. Mag.* 30, 316-20(1915).—No Stark effect was found with 50000 v./cm. for crystals of fluorite, ruby, monazite, Pr₂(SO₄)₃, Nd₂(SO₄)₃, Nd(NO₃)₃, and UO₂(NO₃)₂. The ruby lines, λ 6918, 6932, showed

corresponding absorption, synchronous resonance, and a decided Zeeman effect, but the fluorite line λ 5736 showed none of these and may not be a normal mode. G. L. W.

Absorption spectra of various derivatives of benzoic acid. J. E. PURVIS. *J. Chem. Soc.* 107, 966-73(1915); cf. *C. A.* 8, 2637, 3025; 9, 207, 2030.—The substances examd. were $C_6H_5CH_2COOH$, C_6H_5COOH , mandelic acid, cinnamic acid, phenylpropionic acid, and the *o*-, *m*- and *p*-forms of toluic acid, $C_6H_4ClCOOH$, $C_6H_4BrCOOH$, C_6H_4ICOOH , $C_6H_4NO_2COOH$ and nitrocinnamic acid. The app. has been described before; the condensed Cd spark was used as the source of light. Curves were drawn showing oscillation frequency against log. relative thickness of the alc. solns. The fundamental vibrations of the atoms in a mol. are influenced by the type and nature, as well as by the orientation and physical conditions, of the system, and the final adjustment of the oscillations producing absorption is controlled by these conditions and by the radiant energy which sets the vibrations in motion and reacts differently on the various atoms and atomic groups. The movements which determine the nature and extent of the absorption are modified by the interdependence and relationships of the various oscillating centers. Some centers, like NO_2 groups and the ethenoid linking, are more powerful than others in modifying the properties of a nucleus. Although there are various differences in the toluic acids, the introduction of I, as in C_6H_4ICOOH , does not destroy the bands as it does in C_6H_4 and $C_6H_5CH_3$. The introduction of I has more influence than Cl or Br, as shown by the decreased persistence and strength of the less refrangible band of the *o*- and *m*-compds. and the greater strength of the more refrangible band of the *p*-compd. The sepn. of the nucleus and the acid group by aliphatic chains has enabled the C_6H_5 nucleus to regain some of its former freedom (whereby the residues of various C_6H_5 bands are produced), but the type of intervening radical modifies the strength and persistency of the bands. E. B. MILLARD.

Fluorescence of frozen solutions of uranyl salts. H. L. HOWES. *Phys. Rev.* 6, 192-206(1915).—The changes produced in the spectra of aq. solns. of uranyl salts by slowly lowering the temp. from that of the room to liquid air temp. are: (1) a proportionate increase in the intensity of all the bands; (2) a shift either toward the red or the violet; (3) a narrowing of the bands, and in some solns. a tendency toward resolution; and (4) a slight change in the frequency interval between bands, although this appears to be const. at any given temp. The only exception to (4) is the fact that occasionally an extreme red or blue band does not join the const. interval series. A suddenly cooled soln. of $UO_2(NO_3)_2$ has a spectrum different from that of the same soln. slowly cooled. This is also true of the double nitrates. Diln. with acid produces larger shifts than diln. with H_2O and often radically changes the appearance of the bands. Alc. solns. invariably give dim, broad-banded spectra. On the basis of the (assumed) formation of different hydrates, the formation of different spectra by the same soln. could be explained. The extraordinary shifts and other changes in the spectra are most readily explained (cf. Nichols and Merritt in a paper to appear shortly) by assuming that the bands in such spectra are complex, and consist of overlapping components which vary relatively in intensity with changes in temp. A Hilger const-deviation spectroscope was used with a special Cu app. which enabled the temp. of the specimen to be kept at any desired (const.) temp. between 0° and -180° . Fluorescence was excited by rays from a C arc which had passed through a water cell, a focusing condenser and a soln. of ammonia- $CuSO_4$ which absorbed all of the exciting light of wave length greater than 0.478μ , so that the fluorescent light from the collimator of the spectrometer could be viewed on a black background. E. B. MILLARD.

Can the dissociation theory be applied to solid solutions in steels (CAMPELL) 9?
Rate of evaporation of ether from oils (BASKERVILLE) 11A.

3. RADIOACTIVITY.

WILLIAM H. ROSS.

The distribution of the active deposit of thorium in an electric field. G. H. HENDERSON. Dalhousie Univ., Halifax, N. S. *Trans. Nova Scotian Inst. Sci.* 14, 1-16(1914-15).—A new type of vessel for this kind of work has been developed and its advantages noted. It has been shown that in dry air all the Th rest atoms are initially positively charged. In pure Et_2O vapor all the Th rest atoms are initially uncharged, and in a mixture of Et_2O vapor and air the charged condition of the rest atoms depends on the relative amounts of Et_2O vapor and air present. The same appears to be true with H_2O vapor.

H. JERMAIN CREIGHTON.

A physical measurement of X-rays. HOWARD L. BRONSON. Dalhousie Univ. Halifax, N. S. *Trans. Nova Scotian Inst. Sci.* 14, 17-29(1914-15).—It has been shown that the action of Röntgen rays on a photographic plate and on a Sabouraud pastille is proportional to the ionization produced in the air immediately surrounding them. A simple app., making use of this principle, has been devised for measuring the intensity and hardness of the rays. It has also been shown that this same app. can be easily used to det. the length of time of exposure needed to produce radiographs of suitable density.

H. JERMAIN CREIGHTON.

Electrical density and absorption of beta rays. FERNANDO SANFORD. Stanford Univ. *Science* 42, 130-1(1915).—Evidence is given to show that the absorption coeff. of the elements for β -rays is dependent rather upon the electrical d. of the absorbing agent than upon its mass d. The former is obtained by dividing the at. charge of an element by its at. vol. in the solid state. This calcn. has been made for 11 of the elements included in the list of 32 elements whose absorption coeffs. for the β -rays of U were detd. by Crowther (*Phil. Mag.* 12, 379(1906)). It is thus seen that for these elements the values of the ratio of λ/D_e , where D_e is the electrical d., vary less from a mean value than do the values obtained for λ/ρ .

W. H. ROSS.

The asymmetric distribution of the secondary electronic radiation produced by X-radiation. A. J. PHILPOT. Univ. London. *Proc. Phys. Soc. London* 26, 131-6(1914).—The extent of asymmetry was investigated with radiations whose mass absorption coeffs. in Al vary from 0.5 to 5. In general, increase in hardness of exciting radiation corresponds with increase in asymmetry.

PAUL D. FOOTE.

A Röntgen tube without the rise of starting potential. J. E. LILLENFELD. *Ber. K. Sach. Ges. Wissenschaften, Leipzig* 66, 76-9(1914).—A Röntgen tube is described which produces a narrow beam of cathode rays of uniform velocity. A hot wire electrode, Ta or W, a pierced cathode, and the anticathode are mounted in a line, the wire electrode in one chamber, the anticathode in another chamber, and the pierced cathode in a neck connecting the 2 chambers. The electrons emitted by the electrically heated wire are driven through the hole in the cathode by an auxiliary field and are then accelerated to the anticathode by the high field in the main discharge chamber.

PAUL D. FOOTE.

Dielectric losses with the cathode ray tube. JOHN P. MINTON. *Proc. Am. Inst. Elec. Eng.* 34, 1115-65(1915).—It is shown that the cyclograph is well adapted to the detn. of dielectric losses in insulation. The watts do not vary as the square of the voltage but may vary from the 1.32 to the 2.52 power of the voltage. Empirical equations are derived that will express the dielectric losses, currents and power factors as functions of the voltage, temp. and absorbed moisture.

Radiography of metals (DAVY) 9. Radioactive minerals in eastern Canada (ROBINSON) 8. Occurrence of radioactive minerals in Ontario (BRUNTON) 8.

U. S., 1,151,187, Aug. 24. B. KETMAN. Obtaining radiothorium and solutions containing thorium-X. The material under treatment is pptd. with NH_4OH and the mixt. of ppt. and supernatant liquid thus obtained is evapd. to dryness and washed with H_2O to remove the NH_4 salts and leave a dense pure radiothorium hydroxide from which a soln. containing Th-X is made by treatment with H_2O or dil. NaCl soln. and shaking.

Brit., 10,083, Apr. 23, 1914. GES. FÜR ELEKTRO-OSMOSE. In obtaining radium salts, the ions adsorbed in colloids are exchanged for other ions by treatment with a soln. of an electrolyte, the exchange being made selective by choosing suitable salt solns. at suitable concns. so that closely related elements, such as the rare earths, may be sepd. In an example, a MnO_2 adsorption product of Ra and Ba in a fine state of division is boiled with an NH_4Cl soln. of stated strength. The solid matter after filtration is stated to contain 32.7% of the Ba and 64.7% of the Ra originally present.

Ger., 281,380, July 24, 1913. C. SCHMIDT. Process of visualizing the α -rays upon the surface of radioactive substances, or material which contains a radioactive substance.

Ger., 282,619, Feb. 18, 1914. R. FÜRSTENAU. Addition to 280,709 (C. A. 9, 1876). Modification of a device for measuring Röntgen rays.

Ger., 282,578, Feb. 20, 1914. G. BUCKY. A fluorescent mass for application to a screen for Röntgen rays contains particles of metals, preferably in the colloidal state, metal powder, or metallic salts, of such properties that when the Röntgen rays impinge thereupon, comparatively feeble secondary Röntgen rays are given off by the metal atoms in large amt.

4. ELECTROCHEMISTRY.

COLIN G. FINK.

Electrochemistry and electric heating as applied to the metallurgical industry. F. FORSTER. *Electrician* 75, 778(1915). C. G. F.

Electro-metallurgical industries as power consumers of electric power. D. A. LYON AND R. M. KEENEY. *Bull. Am. Inst. Min. Eng.* 1915, 1707-30.—For ferro-alloys hydro-elec. power is high in U. S. and not favorably located for receipt of raw material and sale of products. For pig Fe, the process is practical only where charcoal or coke is high priced. The treatment of Cu and Zn ores is still in the exptl. stage. The West offers few advantages for the electro-metallurgical industries, but development on non-ferrous materials seems promising. W. H. BOYNTON.

Electric iron ore smelting in Sweden. J. A. LEFFLER. *Electrician* 75, 729(1915); *Engineering* 100, 131-3(1915).—A statement of the present condition of this industry. C. G. F.

The principal electric furnaces for the preparation of steel and wrought iron. O. DIEFFENBACH. *Chem. App.* 2, 149-52, 161-4, 173-6(1915).—Descriptions, with 21 cuts, of the Stassano, Héroult, Girod, Kjellin and Röchling-Rodenhauser furnaces. J. H. MOORE.

Electric furnaces for reheating, heat treatment and annealing. T. F. BAILY. *Proc. Eng. Soc. W. Pa.* 31, 255-72(1915); *Met. Chem. Eng.* 13, 558-64(1915).—A general discussion, special attention being drawn to the advantages of the elec. furnace for these purposes. E. J. C.

Electrothermic iron ore smelting in Scandinavia. ANON. *Eng. Mining J.* 100, 351-2(1915).—A discussion of the present status of elec. smelting to produce pig iron in Norway and Sweden. E. J. C.

Electric furnace for gold refining at the Alaska Treadwell cyanide plant. W. P. LASS. *Bull. Am. Inst. Mining Eng.* 1915, 1443-50.—Au ppt. from the Zn dust process is treated by the Pb smelting method. The furnace is constructed from an old acid drum by cutting over the top and introducing a Cu cable through the bottom and spreading the strands fan-shaped on the inside of the drum. Powdered graphite mixed with 10% cement is tamped wet into the bottom, around and covering the Cu wire. Graphite is carried to the bottom of the Pb well and acts as lower electrode. The melting chamber 14" × 20", is firebrick; upper electrodes of graphite or C 3" × 4" are arranged with threaded joints, enabling new electrodes to be connected without shutting down or wasting stubs. The cover has openings for charge feed, gas escape and electrode introduction. The furnace is operated on a lighting circuit through a 50 kw. transformer. A H₂O rheostat is used to regulate the amp. when furnace is started and later when the metal bath would conduct enough current to cause a short circuit. The charge consists of by-products 100 parts, old reverberatory hearths 20, PbO 20, coke 2, scrap Fe 3. The furnace acts like the arc type until hot. The charge is added and electrodes raised as the load increases until the entire chamber is filled with the charge and the upper electrodes extend about 1 ft. into the melt. The furnace automatically becomes one of the resistance type. Molten Pb and slag are tapped as in a blast furnace. Coke is the only cost, since cupels and mill scrap furnish PbO and Fe. Advantages claimed over blast furnace are: a saving in mechanical loss of Au due to neutral atm., a low grade slag giving quiet melting action, nicety of melting temp. regulation, and health benefit to operators.

W. H. BOYNTON.

Synthesis of nitrogen oxides in the electric arc. E. ROELLER. *Rev. Electrochim. Electrometall.* 8, 33-50, 97-117(1914).—A review.

C. G. F.

The effect of wave form upon the chemical action of the silent electrical discharge in ozone formation. G. LECHNER. *Z. Elektrochem.* 21, 309-24(1915).—L. first gives a historical review of the subject, then a discussion of the various forms of curves and their evaluation, detn. of O₃ obtained and the method of carrying out the expts., which were conducted at atm. pressure and room temp., using both a glass tube and a Au-plated brass tube. Both a. c. and interrupted d. c. were employed. It was found that when a. c. was used with the metal tube a partial rectification took place. By a detn. of the form factor of the curves the av. current was calcd. and the law of Warburg and Leithäuser, that the O₃ yield is nearly proportional to the current, was corroborated. The best results were obtained with the flattest wave form curves.

W. E. RUDER.

The hydro-electrolytic treatment of copper ore. R. R. GOODRICH. *Columbia Univ. Bull. Am. Inst. Mining Eng.* 1915, 1551-94; cf. *C. A.* 8, 1917.—Arizona porphyry Cu ore was used in lab. expts. This consisted of pyrite and chalcocite with small amts. of oxidation products: malachite and limonite. Some zircon was present. Analysis: Cu 6.04, Fe 10.9, S 12.70, SiO₂ 65.10%. Of the Cu, 1.7% was sol. in dil. HCl. Petrographic details are given. On the large scale, concn. and smelting had afforded a recovery of 66% of the Cu. By roasting at 600 to 725° all the Cu was extractable by hot 10% H₂SO₄. If the temp. of roasting reached 800°, Cu compds. insol. in that strength of acid were formed. What would pass 80-mesh was sufficiently roasted in 1½ hrs. If somewhat coarse, 2 hrs. were required. As the amts. roasted did not supply adequate quantities of soln., expts. on electrodeposition were made with a soln. of CuSO₄. Depolarization by SO₂ was most efficient when the soln. was satd. with SO₂ and C anode was used. The nature of the anode is important; no depolarization occurred when Pb anode was used. A step arrangement was worked out, by which the Cu deposition could be made continuous, the discharged liquor being barren of Cu.

E. WALLER.

The development of electrolytic copper refining. LAWRENCE ADDICKS. *Trans. Intern. Eng. Congress 1915*, 7 pp. (advance copy).—A brief review. E. J. C.

Electrolysis of solutions of the rare earths. II. L. M. DENNIS AND P. A. VAN DER MEULEN. *J. Am. Chem. Soc.* 37, 1963-76(1915); cf. *C. A.* 9, 560.—Nitrates were used in the previous expts., and no diaphragm was employed, so that the pptn. may have been due to NH_3 formed by reduction of HNO_3 during the electrolysis. About 1200 g. of Yt group oxides, from which Ce and almost all of the Di group had been removed, were added to warm HCl until a neutral soln. was obtained contg. 10% by wt. of the oxides. This soln. was electrolyzed in a large cell with Hg cathode, a porous cup diaphragm and C anode; after passing about 100-150 amp. hrs. through the cell at 9 volts, the pptd. hydroxides were removed, and the electrolysis continued on the remaining soln. Twenty fractions of 25-50 g. each were obtained. The at. wts. of the fractions dropped regularly from 124 in the 2nd fraction to 93 in the 20th. From absorption spectra it was shown that the colored salts Er, Ho, and Th were concd. in the early fractions, a small amt. of Nd which was present was concd. in the later fractions, and almost all of the Yt was pptd. in the last fractions. To det. if the decompn. voltages might be used to effect a sharper sepn. than the higher voltage employed in the expts., the decompn. potentials for the nitrates between Pt terminals were detd. as follows: Th 1.87 v., Nd 2.03 v., La 2.05 v., Ce^{III} 2.18. Two expts. were made with chlorides, giving Th 1.94, Ce^{III} 2.36. Fractional electrolysis of some nitrate solns., using a diaphragm, showed a sepn. similar to that obtained with the chlorides. The rate of pptn. was 4 times as great as from the chlorides, though NH_3 was shown to be absent. Fractional electrolysis of a soln. high in Er, Ho, Tm and Yt gave, in a series of 6 fractions, no appreciable sepn. of the first 3 from one another, but rapidly eliminated the Yt. In these expts. the hydroxides of the earths are pptd. in the order of the basicities of the earths. Rapid concn. of certain groups is attained in a short series of fractions. E. B. MILLARD.

The hypochlorite-carbon cell a new type of primary cell. A. THIEL. *Z. Elektrochem.* 21, 325-9(1915).—An analysis of the process of Hofmann and Rifter by which amorphous C is changed, by means of a powerful oxidizing agent, into CO_2 at room temps. with the production of available elec. current. It is shown that the principle reaction is not directly between the reagents hypochlorite and C, but upon the oxidation potential of the hypochlorite against the O liberated upon the C. The C electrode then acts as a depolarizer and uses up the O, forming CO_2 . The new cell is then a half electrochem. oxidation-reduction series. It is possible, therefore, that the O of the hypochlorite can be replaced by compressed atm. O of the same oxidation potential. It has not yet been possible to obtain elec. energy quantitatively corresponding to the energy obtained from burning the C. It is not necessary to look for electrochem. reactions at both electrodes; the reaction of depolarization may be a purely chem. one. The iodoform and nitrobenzene elements are given as other examples. In both of the cases the chem. depolarization takes place at room temp. W. E. RUDER.

Home-made charging panel for small batteries. ANON. *Elec. World* 66, 591 (1915); illus.—A set of series-parallel Ward-Leonard resistance units designed to fit Edison sockets are used in place of a lamp bank. C. G. F.

Gold and platinum plating. M. KATERIDGE. *Metal Ind.* 13, 108-9(1915).—Au is dissolved in *aqua regia*, diluted, pptd. with NH_4OH with const. stirring, washed and dissolved in KCN. It is made up so that 1 oz. of stock soln. contains 5 dwt. Au (or 195 g. Au per l.). A cheap acid-proof Au bath contains $\text{Ni}(\text{CN})_2$ and Ni anodes are used. Cu and Ag cyanides are used for rose and green Au effects. For Pt plating, the soln. contains Na_2HPO_4 , Na_2CO_3 , NH_4Cl and $\text{Na}_2\text{B}_4\text{O}_7$ and PtCl_4 , 2 dwt. in 1 qt. (or 3.3 g. per l.). W. H. BOYNTON.

Preparation and operation of leadplating baths. F. C. MATHERS. *Metal Ind.* 13, 184-5(1915).—A résumé of the different plating baths. Alk. baths are unsatisfactory. The simplest and cheapest bath contains 13 oz. $\text{Pb}(\text{NO}_3)_2$, 7 oz. concd. AcOH and 3 oz. of the gummy residue remaining from the extn. of aloes. This residue is dissolved by warming in AcOH , and is then added to the $\text{Pb}(\text{NO}_3)_2$ dissolved in 1 gal. H_2O . The bath is used without filtering. The deposit is fine and smooth, but brittle when thick. For successful plating, the bath should be kept strongly acid, anodes should be placed in closely woven cloth bags, and should be suspended by Cu wires reaching into the soln. W. H. BOYNTON.

A twentieth-century electroplating plant. G. W. GRUPP. *Metal Ind.* 13, 331-4 (1915).—An illustrated description of the Spirella Co.'s plant at Niagara Falls, N. Y., where a modern and splendidly equipped plating dept. is maintained. Excellent ventilation is procured by a fan system. W. H. BOYNTON.

Nickel-plating on zinc. W. H. WEBER. *Metal Ind.* 13, 336(1915).— NiSO_4 is reduced at the cathode to NiS , producing black streaks on the work. These are eliminated by substituting the following soln.: NiSO_4 8 oz., K or Na citrate 4 oz., NaCl 2 oz., H_2O 1 gal. or 60 g., 30 g., 15 g., resp., in 1 l. H_2O . Good results are obtained by adding NiCO_3 to neutralize free acid and 4 oz. alkali citrate. W. H. BOYNTON.

Bar nickel anodes vs. flat. J. A. HALL. *Metal Ind.* 13, 336(1915).—Bar anodes are best because they cause greater corrosion and less scrap, and may be used as long as Ni remains to be dissolved. W. H. BOYNTON.

Electroplating with cobalt. C. H. BUCHANAN AND T. HADDOW. *Metal Ind.* 13, 240-2(1915).—A historical sketch of the development. The deposit is of close grain and good color. $(\text{NH}_4)_2\text{SO}_4\text{CoSO}_4$ is used, adding CoSO_4 at intervals to replenish the electrolyte. H_3BO_3 and MgSO_4 serve as addition agents. The plate is smooth and stands bending. W. H. BOYNTON.

Removing grease by electricity. T. BROWN. *Metal Ind.* 13, 192-4(1915).—A steel or Fe tank is used, with steel, C or Cu electrodes and heating coils at the sides, but not touching. The work is hung on the cathode rod and the full v. used. The electrolyte (soda or potash) should be kept near the b. p. Machine oil must be scooped off the top of the soln. For removing baked enamels, japan, etc., NaOH or KOH soln. is used with c. d. 10-20 amp. per sq. ft., v. 6-12. W. H. BOYNTON.

Electrolytic mitigation. ANON. *Am. Gas Light J.* 103, 129-30(1915).—The order of the Manitoba Public Utilities Commission reproduced here shows the latest approved practice in preventing damage to underground cables and mains due to electrolysis by elec. current of the railway system. E. J. C.

The luminous arc lamp. R. B. HUSSEY AND S. C. ROGERS. *Elec. Rev. West. Elec.* 67, 399-403(1915).—A short history of this lamp is given. The lower or neg. electrode contains ilmenite to which a little magnetite is added to maintain the desired relative proportion of Fe to Ti. The magnetite, ilmenite, and chromite are first separately ground and purified and, from the analysis of each, correct proportions are mixed in a ball mill. This powdered mixt. is then packed into iron tubes for use. With the newest type an efficiency of 20 lumens per watt may be obtained at 4 amps. and 32 lumens per watt at 6.6 amp. These lamps need trimming and cleaning about once a month. The upper or positive electrode is usually made of hard drawn Cu in a steel or brass sheath. Various forms of reflectors and systems of illumination are described. W. E. RUDER.

Present status of arc lamp carbons. V. A. CLARKE. *Elec. Rev. West. Elec.* 67, 406(1915). C. G. F.

Modern arc lamps. C. E. STERNBERG. *Elec. Rev. West. Elec.* 67, 409(1915).—A review. C. G. F.

Effect of small quantities of methane and carbon monoxide upon the life of nitrogen-tungsten lamps. L. HAMBURGER. *Z. angew. Chem.* 28, I, 291-5(1915).—It is shown that the presence of small percentages of CH_4 (0.04-0.27) and CO in the N gas has a decided detrimental effect upon the life of the half-watt gas-filled W lamp. W carbide is formed in both cases and this is decomposed at the high temp. of operation, C being deposited upon the bulb. The filament becomes brittle and the resistance is increased.

W. E. RUDER.

Mazda C lamps and illumination progress. ANON. *Elec. Rev. West. Elec.* 67, 397(1915).—Present status of the N-filled W lamps is discussed. C. G. F.

The theory of oscillation valves and gas relays. R. S. WILLOWS. *Electrician* 75, 742(1915); see fig.—The relay described by De Forest and that described by Reisz are shown to be the same in physical principle. In the Reisz form the secondary terminals normally joined at B and C, are placed in series with a battery of about 30 v., B being connected with the positive pole. The terminals A, C of the valve

are connected to a battery of 200-300 v. in series with a telephone or another oscillation transformer. The current is dependent upon a plentiful supply of negative ions from the neighborhood of the cathode. Since the negative ions move much faster than those of opposite sign, there results an excess of positive charge in the gas which is most pronounced just in front of the cathode. This causes the elec. field to be more intense here than in any other part of the tube so that it is possible for positive ions also to produce others either by collisions or bombardment of the cathode surface. With a hot lime cathode the field is never so large as when a plain cold metal is used. Lime cathodes are constantly emitting

or absorbing gas, thus making it difficult to maintain constant sensibility, so it is predicted that a hot carbon or metal filament will be found more trustworthy though less sensitive.

W. E. RUDER.

Steel-reinforced aluminium cables. E. T. DRIVER AND E. V. PANNELL. *Elec. World* 66, 524-6(1915).—It is shown that this type of cable is now far beyond the exptl. stage, two companies alone using over 7,000,000 lbs. Owing to the compd. nature of the wire, it does not possess constant physical properties. Tables and curves are given whereby the sag and stress may be calcd. allowing a sufficient factor of safety with ice $1\frac{1}{2}$ in. thick and a 70 miles p. hr. wind.

W. E. RUDER.

Brit., 9,046, Apr. 9, 1914. J. VON KOWALSKI-WIERUSZ. **Ultraviolet rays for sterilizing,** effecting chem. reactions, or other purposes, are produced by a "damped" spark discharge of a large elec. current alternating with a frequency corresponding to an electro-magnetic wave length of less than 3000 meters. Damping may be effected by injecting gas into the spark-gap, or by using electrodes of particular materials. Ni, Co, W, V, Fe, Zn, Cd, Al, Mg, Mn, or alloys of these, especially with rare-earth metals, are suitable. Zr, W, and Mo may be used in an inert gas such as H or N. Materials which do not readily disintegrate, such as the Ni-steel alloy "invar," are also advantageous. The 2 electrodes may be of different materials. A silica or other partition may be placed between the spark-gap and the substance treated, when the substance must not be exposed to N oxides. Water to be sterilized may be passed through an open channel beneath a row of naked spark-gaps. The electrodes may also be immersed in the liquid to be treated. A Ni spark-gap may utilize 2 kw.

Brit., 9,846, Apr. 21, 1914. W. H. JAMES. **Electrolyzing brine or other soln. of a mineral acid salt,** with sepn. of the products at the opposite electrodes, one product being used for lixiviation of ore, Sn scrap, or other material containing base metals, while the other product is used for pptg. a compd. of the metal from the soln. obtained and thus regenerating the original electrolyte. For scrap or Cu ore, the anode liquid is used as solvent, for arsenical ores, the cathode liquid. Graphite from the ore may be removed by skimming. From the residues, other metals such as Au can be recovered.

Brit., 10,171, Apr. 24, 1914. V. SCHOLZ. In mfg. **galvanic batteries,** colloidal graphite is employed with a depolarizer such as MnO₂, particularly in dry cells, to ob-

tain a more nearly uniform e. m. f. suitable for running table lamps, etc. Colloidal graphite may be obtained by Bredig's method of elec. pulverization, or by Kuzel's process of subjection to acids or alkalis.

Brit., 10,193, Apr. 24, 1914. DEUTSCHE GOLD and SILBER-SCHNEID-ANSTALT VORM. ROSSLER. An electric furnace for obtaining alkali metals, which is described in 13,356, 1890, is modified for the electrolysis of alkali halogen compds. by coating the alkali metal collector with a mixt. of 1 or more salts with substances such as CaO , MgO , or asbestos fiber, unattacked by the anode products such as Cl . To retain the coating in a solid or pasty condition, the collector is cooled by H_2O , steam, or air, or otherwise.

Brit., 10,287, Apr. 25, 1914. E. GERBEL-STROVER. In electric furnaces for fusing alumina, etc., composed of a number of receptacles adapted to be connected column-wise, means are provided for supporting the column vertically so that the lowest section may be removed to expose a part of the solidified material, which is then broken off, the app. being worked continuously.

Brit., 10,415, Apr. 27, 1914. J. DAVIES and A. GALLINKAMP. An electric furnace comprizes end walls coupled together by pairs of tie-rods, a tube, muffle, or similar receptacle supported by the end walls and heated by a resistance, and removable lagging blocks. Each end of the resistance is connected to 1 of the tie-rods, to which terminals are fixed. The furnace may be provided with an expansion thermostat consisting of a metal rod lying close to the heater; the rod is secured to 1 end wall and passed through the other, which carries an adjustable screw engaging the end of the rod so as to make or break a circuit controlling a visible or audible alarm, or to cut off or reduce the heating current. Connection to the end of the thermostat rod is made by 1 of the tie-rods. The adjustable screw may be secured in any position by a lock nut. The furnace is enclosed in a sheet metal or like casing, preferably without end walls; the casing is mounted on supports and is provided with a removable cover. The removable lagging blocks may be of MgO -asbestos, and the end walls of urallite. The tube may be of fused silica or clay. In a modification, the furnace is arranged vertically, the tube being replaced by a crucible.

Brit., 10,616, Apr. 29, 1914. E. ACHENBACH. An alkaline electrolyte of strength say between 25 and 50° Bé. is thickened by adding 10% of CaO or MgO and heating to 100° . The product is used in dry cells, with CuO or MnO_2 , or other depolarizers. Cf. C. A. 9, 1880.

Brit., 10,980, May 4, 1914. G. A. ASHCROFT. In electrolysis, a fused mixt. of an alkali hydroxide and an alkali cyanide, with or without other salts, is used as electrolyte with an anode of an alkali metal alloy, prepared in another cell. Suitable proportions are: 60 parts of NaOH and 40 of NaCN , or 63 of NaOH , 30 of NaCN , and 7 of Na_2CO_3 or NaCl . With 100 kg. of electrolyte, a current of 10,000 amp. may be used. The Pb alloy may contain 5-10% of Na. Both the electrolyte and the alloy are kept in motion.

Ger., 283,957, Dec. 18, 1913. HENKEL & CIE. In the production of hydrogen peroxide by electrolysis under increased pressure, the interior wall of a high pressure vessel, tubular in form and made of a suitable metal, is coated with a suitable electrode material and serves as cathode, while an anode, coated with a suitable diaphragm film, is disposed approx. in the middle axis of the vessel. The construction is illustrated in detail. Cf. C. A. 9, 272, 1013.

Ital., 134,266, July 25, 1913. B. SZILARD. In an electrolytic process for recovering mercury from poor ore, the pulverized material is treated with a soln. of NaCl and CaSO_4 . After the product has been allowed to stand for two days, a current

of air is passed through it. The liquid which contains the Hg salt may be subjected to electrolysis.

Ital., 139,705, Feb. 16, 1914. G. CLÉMENT. In a process and app. for separating or concentrating the rare earths (Au, Pt, U, etc.) from powdered material containing them, the material is subjected to an elec. discharge of high tension between 2 surfaces, until a coating, containing the material, appears on 1 surface. The metallic particles are attached to the coating. The gang is discarded.

6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

Behavior of phosphoric acid with calcium hydroxide. I. M. KOLTHOFF. Utrecht. *Chem. Weekblad* 12, 662-6(1915).— H_3PO_4 can be titrated with $\text{Ca}(\text{OH})_2$ as a unibasic acid, or vice versa, using dimethylaminoazobenzene as indicator, but titration as a dibasic acid with phenolphthalein is not practicable, because of hydrolysis of CaHPO_4 and formation of $\text{Ca}_3(\text{PO}_4)_2$. When H_3PO_4 is titrated to an end point with phenolphthalein while boiling, a quaternary compd., probably $4\text{CaO} \cdot \text{P}_2\text{O}_5 \cdot 5\text{H}_2\text{O}$, is formed.

G. W. MORRIS.

Halogen compounds of molybdenum and tungsten. X. The cyanides of tungsten and molybdenum. The valence of the central atom in their complex anions. A. ROSENHEIM AND E. DEHN. *Ber.* 48, 1167-78(1915); cf. *C. A.* 8, 1395.—In the prep. of $\text{K}_3\text{W}_2\text{Cl}_9$, from which the cyanide is easily prepared, the authors use the following improvement over Olsson's method: 50 g. of K_2WO_4 in 15-20 cc. H_2O are poured into 1 liter of concd. HCl heated to 90° and thoroughly shaken. The soln. is satd. at 60° with HCl and then reduced with granulated Zn. The soln. becomes brownish green in color after 1.5 hr. It is again satd. at 0° with HCl and left standing at that temp. for several days in a closed flask. After 2 days, 26-28 g. $\text{K}_3\text{W}_2\text{Cl}_9$ sep. out. The cyanide may be prepd. from $\text{W}(\text{OH})_2(\text{SNC})_2(\text{C}_6\text{H}_5)_2$ made by dissolving 10 g. $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$ and 25 g. NaSNC in 200 cc. H_2O and acidifying with 50 cc. HCl (1.12). The addition of small quantities of pyridine causes the sepn. of a dark green oil, which on standing at 0° , becomes a mass of dark green crystals. These are washed by decantation with H_2O several times, then with EtOH and Et_2O . The detn. of valence by means of ammoniacal AgNO_3 indicates that the W is pentavalent in this compd. From the soln. of this salt the Cd salt, $[\text{Cd}(\text{NH}_3)_2]_2[\text{W}(\text{CN})_8] \cdot 2\text{H}_2\text{O}$ may be pptd. From a conc. soln. of the K-salt, $\text{K}_4[\text{W}(\text{CN})_8] \cdot 2\text{H}_2\text{O}$, the corresponding acid may be prepared upon satn. with conc. HCl and rapid cooling. The ppt. formed is dissolved in a small amt. of abs. EtOH and the yellowish soln. shaken with Et_2O . The crystals which sep. when the resulting oil is cooled are dissolved in a little H_2O and HCl is passed in at 0° . Yellowish crystals which, after drying over KOH, have the comp. $\text{H}_4[\text{W}(\text{CN})_8] \cdot 6\text{H}_2\text{O}$, separate. Expts. carried out by the authors to det. the valence of W and Mo in their complex cyanides by means of the ammoniacal AgNO_3 method disclosed the facts that (1) the ppt. of metallic Ag is contaminated with small amts. of silver molybdate or tungstate from which it is difficult to free it, (2) the ppt. of metallic Ag is not sol. in the hot NH_4OH with which it is washed. As a result of valence detns. carried out with these cyanides, the authors reach the conclusion that the valence of the central W or Mo atom must lie between W^{V} and W^{VI} or Mo^{V} and Mo^{VI} .

L. T. FAIRHALL.

Dissertation on the rare earths. C. R. BÖHM. *Z. angew. Chem.* 28, I, 356(1915).—A list of 23 references to the literature, supplementing a formerly published bibliography (cf. *C. A.* 6, 1575).

E. J. C.

The preparation of sodium selenate and selenic acid. J. MEYER AND K. HEIDER. *Ber.* 48, 1154-8(1915).—The pure sublimed SeO_2 used by the authors was always prepared by the oxidation of freshly pptd. Se with fuming HNO_3 . Na_2SeO_4 was prepared by treating SeO_2 with the calcd. amt. of Na_2O_2 . A violent reaction occurred yielding a brownish fused mass which soon whitened. This mass, which consisted in the greater part of Na_2SeO_4 , was dissolved in H_2O , treated with CO_2 to remove the excess Na_2O_2 and NaOH and $\text{Al}(\text{OH})_3$ (from the porcelain crucible), filtered and recrystd. several times. During the last crystns. the temp. was maintained above 30° in order to avoid formation of salt holding much H_2O of crystn. The crystals were dried till water-free. The salt thus purified was analyzed by reducing to H_2SeO_4 with HCl , then to Se with $\text{N}_2\text{H}_4 \cdot \text{HSO}_4$ and weighed in a Gooch crucible. For the oxidation of SeO_2 with H_2O_2 0.6 g. of the oxide was treated on the steam bath with 1 g. perhydrol. The SeO_2 goes into soln. with evolution of O. The resulting H_2SeO_4 was pptd. from HNO_3 soln with BaCl_2 and weighed as BaSeO_4 . 47% of the SeO_2 had been converted into H_2SeO_4 by this means. The electrolytic oxidation of SeO_2 was carried out using for anode Pt foil having a surface of 6 sq. cm. and for cathode Pt wire. 3.2 g. of SeO_2 were dissolved in 30 cc. conc. HNO_3 (1.42). Temp. = $70-80^\circ$. P.d. = 8 v. One cc. of the soln. was analyzed from time to time by pptn. as BaSeO_4 and weighing. The H_2SeO_4 first formed appears to hasten the formation of more acid catalytically. Further expts. in which a few drops of pure H_2SeO_4 were added before electrolysis distinctly accelerated the anodic formation of H_2SeO_4 .

L. T. FAIRHALL.

Heteropoly acids containing vanadic acid. III. W. PRANDTL. Munich. *Ber.* 48, 692-8(1915); cf. *C. A.* 6, 838; 7, 1452.—A formulation of the tungstates completely analogous to that of the vanadates and molybdates is presented. The analytical data of various investigators are collated and shown to agree, on the whole, best with this formulation. There are no mol. wt. detns. available in this case but for the vanadates the analogous formulation is in entire agreement with the mol. wts. as found. This article contains no new exptl. work.

A. R. MIDDLETON.

Heteropoly acids which contain vanadium. IV. WILHELM PRANDTL. Munich. *Z. anorg. allgem. Chem.* 92, 198-212(1915).—A discussion of a number of complex vanado-tungstate compds., to which new formulas are assigned.

G. W. M.

Compounds of arsenious oxide. II. F. A. H. SCHREINEMAKERS AND W. C. DE BAAT. *Proc. Akad. Wetenschappen* 18, 126-32(1915).—Isotherms in the systems $\text{H}_2\text{O}-\text{As}_2\text{O}_3-\text{KCl}$, $\text{H}_2\text{O}-\text{As}_2\text{O}_3-\text{NH}_4\text{Cl}$ and $\text{H}_2\text{O}-\text{As}_2\text{O}_3-\text{NaCl}$ were detd. at 30° by shaking together in a thermostat H_2O , As_2O_3 , and the chloride in question. In the first case, the compd. $(\text{As}_2\text{O}_3)_2(\text{KCl})_2$, and in the 2nd case, the compd. $\text{As}_2\text{O}_3 \cdot \text{NH}_4\text{Cl}$, is found, while in the 3rd system NaCl and As_2O_3 are the only solid phases.

G. W. M.

The action of alkali sulfide on sodium ethyl thiosulfate. A. GUTMANN. *Ber.* 48, 1162-6(1915); cf. *C. A.* 1, 2556; 2, 2374.—A soln. of 5 g. Na Et thiosulfate in 60 g. EtOH treated with 65 cc. of a freshly prepared EtOH soln. of K_2S (free from polysulfides) reacts with the formation of white cryst. alkali sulfite. A mercaptan odor is noticeable. On warming gently, the sepn. of alkali sulfite is hastened and the soln. becomes intensely yellow. The soln. (a citron-colored EtOH soln. of $\text{C}_2\text{H}_5\text{SSH}$) seps. out whitish yellow S on further heating. On shaking with Na_2AsO_3 or KCN , sodium monosulfoxyarsenite and KCNS , resp., are formed. On continued heating, the above deep yellow colored soln. formed by the action of alkali sulfide, becomes colorless, mercaptan and EtOH distil over and there is left a gray-yellow residue, which gives the reaction for sulfite. Evidently there are formed $\text{SO}_2\text{NaOSC}_2\text{H}_5$, $\text{C}_2\text{H}_5\text{SSH}$, and finally

mercaptan, sulfur and sulfite. By following the reaction quant. the citron-colored soln. is shown to consist of C_2H_5SSK and not of mercaptan, K_2S and alkali sulfite.
L. T. FAIRHALL.

7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

Disintegration of materials by fusion with sodium peroxide. NOAILLON. Liège. *Bull. soc. chim. belg.* 28, 212(1914).—N. discusses the general procedure for the disintegration of materials by fusion with Na_2O_2 in a Fe crucible. During the fusion of certain minerals containing antimonates the surface of the Fe crucible assumed a peculiar appearance which was ascertained to be due to the formation of an alloy of Fe and Sb; an alloy of Fe and Pb was formed in the case of Pb minerals. Inasmuch as the crucible was rather rapidly attacked, N. attempted to employ crucibles with a peroxide surface; the resistance was thereby increased, but the layer of peroxide scaled off considerably.
H. S. PAINE.

The use of red cabbage dye as indicator in chemistry. ECKERLIN. *Mitt. kgl. Landessans. Wasserhygiene* 20, 58-69(1915).—The indicator serves for the detn. of the reaction of a liquid and can be used instead of phenolphthalein, Congo red or rosolic acid. It is red in an acid medium and turns green with alkali. If neutral the color is violet. The indicator is less sensitive to CO_2 than rosolic acid or phenolphthalein, and is more sensitive to alkali than to acid. Since the indicator decomposes readily it is necessary to preserve it by the addition of $CHCl_3$ or C_6H_5OH . Even though preserved the indicator begins to show signs of decompn. after 4 weeks and must be re-adjusted by the addition of very weak KOH.
ARTHUR LEDERER.

The quantitative determination of total sulfur in vegetable substances. D. J. DEJONG. Gröningen. *Chem. Weekblad* 12, 626-34(1915).—The purpose was to select a method which was accurate for amts. of S less than 1% (in this case 0.3 to 0.8%) and which did not give a final soln. containing much inorg. salts to contaminate the $BaSO_4$ ppt. Evapg. to dryness with $KMnO_4$ and KOH was selected and test detns. made to find the optimum conditions. The method adopted is: Treat 20 g. fine material with 80 cc. 1% KOH, warm 15 min. on H_2O bath with stirring, cool and add slowly a cold satd. soln. of 12 g. $KMnO_4$ with stirring. Place in boiling H_2O -bath till the $KMnO_4$ is reduced (about 10 min.). Wash into a 12-15 cm. Ni dish and dry slowly (7 hrs.) over a spirit lamp with a mixt. of 1 pt. MeOH to 2 pts. EtOH; then ignite strongly till no more fumes come off (about 1 hr.). Heat to redness over a Barthel blast, scraping the material to the center, cool, pulverize finely with a porcelain pestle, and ignite again till all C is consumed. Cool completely, grind in H_2O in the dish, and wash into a 300 cc. Erlenmeyer. Add 20 cc. Br-HCl (100 cc. 25% HCl and 5 cc. satd. Br soln.) or enough to acidify, warm some hrs. on the H_2O -bath and filter. Wash with HCl (1 drop 25% HCl to 600 cc.), evap. to dryness, moisten with HCl and dry, repeating this 3 times; then bake at least 1 hr. on the H_2O -bath, and filter off SiO_2 . In the filtrate ppt. $BaSO_4$. The MnO_2 ppt. sometimes occludes S, especially if the soln. stands in contact with it in the cold before filtering. To recover this, treat the ppt. with HCl, warm till dissolved, dil. and filter; then evap. filtrate to dryness, moisten with HCl, dry, take up and filter, and ppt. $BaSO_4$ in the filtrate. Normally not over 2 to 3 mg. $BaSO_4$ should be obtained here, but sometimes as much as 20 mg. are found. The difference between duplicates on straw were: Max. 6, min. 0.8 mg. $BaSO_4$ on amts. ranging from 180 to 470 mg.
W. L. BADGER.

The nephelometric determination of small quantities of phosphoric acid. H. SERGER. Braunschweig. *Chem. Ztg.* 39, 613(1915).—The method has given rapid

and satisfactory results in investigations of polluted streams, but must be carried out carefully. Dissolve 225 g. NH_4 molybdate in hot H_2O and add, with stirring, to 1.5 l. HNO_3 (1:1) in which has been dissolved 600 g. $(\text{NH}_4)_2\text{SO}_4$. Dilute to 3 l. Evap. 100–300 cc. H_2O , according to probable content of P_2O_5 , to dryness in a quartz or Pt dish, treat the residue with 2.5 cc. HNO_3 , filter into a beaker about 8 cm. high and 4 cm. diam., wash the filter with 2.5 cc. HNO_3 , and then add 25 cc. of the molybdate soln. and 20 cc. concd. HNO_3 . The comparison beaker contains the same amts. of molybdate soln. and HNO_3 . Heat both to 70° in a H_2O bath, stirring with small glass rods, and taking care to avoid scratching the beakers. Set the beakers on a black ground and illuminate from one side; run a 0.002 N P_2O_5 soln. (1 cc. = 0.000372 g. P_2O_5) rapidly and carefully, with gentle stirring, into the comparison beaker till the cloudiness is the same in the 2 beakers. The beakers should then be boiled out with a 5% NaOH soln. and rinsed. 90–196 mg. P_2O_5 in 100000 pts. H_2O can be detd. easily and quickly.

J. H. MOORE.

Volumetric determination of phosphoric acid in calcium phosphate. I. M. KOLT-HOFF. *Pharm. Weekblad* 52, 1053–5 (1915).—Dissolve a weighed quantity of the phosphate in dil. HCl , render neutral to dimethylaminoazobenzene and make up to a definite vol. A soln. of Na_2HPO_4 , with the indicator, should be used for comparison. To an aliquot portion add an excess of $\text{Na}_2\text{C}_2\text{O}_4$ soln., neutral to phenolphthalein, then some of the latter indicator, and titrate the soln. with 0.1 N alkali (1 cc. alkali = 7.1 mg. P_2O_5).

P. VAN DER MEULEN.

Quantitative determination of phosphine. II. Gravimetric and titrimetric methods. H. RECKLEBEN. Leipzig. *Z. anal. Chem.* 54, 308–21 (1915); cf. C. A. 9, 2204.— PH_3 was absorbed by 0.16% Cl water or satd. Br water, NH_4OH was then added in excess and the P pptd. with magnesia mixt. 0.5 N I in KI absorbs PH_3 completely but should be allowed to act 24 hrs. and the soln. then heated 30 min. with persulfate or H_2O_2 to insure complete oxidation to phosphate. While titrimetric methods can not be applied with accuracy to the I soln. of PH_3 , the course of the reaction between the I soln. and the absorbed PH_3 can be followed by a detn. of the I used. Directly after absorption the atomic ratio of P to I used is 1:3.2, after 16 hrs. 1:5.5, and after 24 hrs. 1:5.95. This ratio nearly corresponds to the reaction $\text{PH}_3 + 6\text{I} + 3\text{H}_2\text{O} = \text{H}_3\text{PO}_3 + 6\text{HI}$. Expts. were made using solns. of NaClO , NaBrO , HBrO_3 , HIO_3 , AgNO_3 , HgCl_2 , $\text{Hg}_2(\text{NO}_3)_2$ and Cu solns. for absorption and oxidation; they failed to give satisfactory methods. KMnO_4 reacts with PH_3 according to the equation $5\text{PH}_3 + 8\text{KMnO}_4 + 12\text{H}_2\text{SO}_4 = 5\text{H}_3\text{PO}_4 + 8\text{MnSO}_4 + 4\text{K}_2\text{SO}_4 + 12\text{H}_2\text{O}$. The PH_3 is absorbed in a measured quantity of 0.5 N KMnO_4 soln., an excess of standard hot $(\text{COOH})_2$ containing H_2SO_4 is added and after rinsing the glass pipet with the hot decolorized soln. the excess of $(\text{COOH})_2$ is titrated back. The H_3PO_4 is pptd. as molybdate. A large excess of KMnO_4 over that necessary for complete absorption should be avoided. The KMnO_4 should not be acidified before the addition of $(\text{COOH})_2$ on account of the evolution of O . The Cl -water, Br -water, and KMnO_4 methods gave best results gravimetrically. The KMnO_4 method also gave good results volumetrically. Titrimetric detns. cannot be applied to the Cl - and Br -water methods.

L. W. RIGGS.

Molybdic acid recovery. C. G. ARMSTRONG. *J. Ind. Eng. Chem.* 7, 764 (1915).—Evap. the filtered soln. on the sand bath to considerable foaming and to the point where there is just enough soln. left to cover the ppt. and keep Fe in soln. Cool, dilute with $1/2$ vol. cold H_2O , settle and decant. Wash with H_2O by decantation and treat with enough 1:1 NH_4OH to fill the dish. A dark ppt. due to Fe forms. Wash the mass into a large flask, warm slightly and allow to stand with occasional shaking. After 2 hrs. filter and add 5% of the original amt. NH_4OH . The concn. of MoO_3 is detd. with a hydrometer and then sufficient fresh MoO_3 is added to make the concn.

0.2825 g. per cc. (a standard soln.) or the $(\text{NH}_4)_2\text{MoO}_4$ soln. can be evapd. to dryness and roasted at 600° to MoO_3 . Yields are over 90%. ISADOR MILLER.

The preparation of normal hydrochloric acid. L. W. WINKLER. *Z. angew. Chem.* 27, 1, 264(1915).— KHCO_3 is used as a standard. It is purified by spreading out a ground sample in a desiccator containing CaCl_2 and filling the desiccator with CO_2 . At the end of 24 hrs., the sample is mixed and exposed for another 24 hrs. Titration of solns. of such purified KHCO_3 against HCl of known strength gave an equiv. wt. for KHCO_3 of 100.19. W. recommends the use of weighing burets for the standardization. E. W. BOUGHTON.

The iodide method applied to the determination of copper in the presence of tin. R. W. COLTMAN. *J. Ind. Eng. Chem.* 7, 764-6(1915).—Weigh out a sample containing not more than 0.25 g. Cu and boil with 15 cc. HNO_3 (2:1). When the alloy is decomposed add dil. H_2SO_4 equiv. to 3 cc. concd. acid and evap. over an open flame. Drive off HNO_3 to fumes of SO_3 whereupon $\text{Sn}(\text{SO}_4)_2$ and CuSO_4 will sep. out. Remove the flame immediately to prevent spattering. Take up the mass with 25 cc. H_2O , shake and dissolve and again evap. to fuming. Cool, take up with 50 cc. cold H_2O and when all is in soln. add 25 cc. H_2O , 10 cc. KI (40%) and titrate immediately with 0.1 N $\text{Na}_2\text{S}_2\text{O}_3$. This gives Cu. Pb in small amts. does not affect the results. The time consumed is 1 hr. ISADOR MILLER.

Titration of nitrates with ferrous sulfate. F. C. BOWMAN AND W. W. SCOTT. *J. Ind. Eng. Chem.* 7, 766-9(1915).—The sample should contain 0.3-0.6 g. HNO_3 . Place 100 cc. concd. H_2SO_4 (free from nitrates) in a 250 cc. beaker set in H_2O . Run the sample in slowly from a 10 cc. pipet, stirring with the same. Run the FeSO_4 soln. in slowly in a fine stream with const. stirring until the soln. changes from yellow to a faint brown or pink. Rinse out pipet by sucking full of acid and allow to drain. Continue titration carefully to first color change. The end point is clear to 0.05 cc. and different operators should agree within 0.1 cc. Directions are also given for making up the standard solns. The method has been applied to HNO_3 in oleum, the analysis of NH_4NO_3 , NaNO_3 , KNO_3 and mixed acid. With care the error does not exceed 1/300 of the total HNO_3 . The method is unsuitable for traces. ISADOR MILLER.

Note on the determination of aluminium oxide and total aluminium in steel. F. O. KICHLINE. *J. Ind. Eng. Chem.* 7, 806-7(1915).—Because of the action of heat on Al_2O_3 all the Al in steel can be detd. in the insol. residue. Dissolve 50 g. drillings in 200 cc. concd. HCl and 300 cc. H_2O at a gentle heat, boil, allow the insol. matter to settle, filter and wash with hot (1:2) HCl and hot H_2O . Ignite the residue in a Pt crucible. Add 0.5 g. $\text{Na}_2\text{B}_2\text{O}_7$ (calcined) and heat gently to dissolve Al_2O_3 . Add 5 g. Na_2CO_3 and fuse again. Dissolve the melt in hot H_2O and det. Al_2O_3 as usual. I. M.

Qualitative separation and identification of arsenic, antimony and tin. F. L. HAHN. Frankfurt a/M. *Z. anorg. allgem. Chem.* 92, 168-70(1915).—The method is based primarily on the sepn. of cryst. $\text{Na}_2\text{H}_2\text{Sb}_2\text{O}_7$ from an alk. soln. when treated with H_2O_2 . The mixt. of As_2S_5 , Sb_2S_5 , SnS_2 and S obtained by pptn. from the yellow $(\text{NH}_4)_2\text{S}_x$ soln. in the ordinary way is extd. cold with 5% Na_2S , the undissolved S filtered off, twice as much 10% NaOH added as is necessary to dissolve the total sulfides, and H_2O_2 added in excess, heating if necessary. After a short time glittering crystals of $\text{Na}_2\text{H}_2\text{Sb}_2\text{O}_7$ form, the sepn. being made complete by diln. of the soln. with 25% of its vol. of EtOH . Filter, evap. off the EtOH , ppt. Sn with NH_4NO_3 , boil to complete pptn., filter, and ppt. As as $\text{NH}_4\text{MgAsO}_4$. The As and Sb ppts. are recognized by their form; the Sn by means of Zn and HgCl_2 . GEORGE W. MORREY.

New reaction for hydrogen peroxide. K. SPIRO. Univ. Strassburg. *Z. anal. Chem.* 54, 345-7(1915).—The addition of a few drops of 0.1 N H_2O_2 and of freshly

prepd. 0.01 *N* FeSO₄ to a dil. phenol soln. is followed by an intense green color, which upon the addition of dil. NH₄OH, (NH₄)₂CO₃ or Na₂CO₃ is changed to reddish violet. Acids change this to green and alkalis change the green back to violet. Many other monohydroxy derivs. of C₆H₅ may be used in place of phenol, *e. g.*, cresol, *p*-hydroxybenzoic acid, tyrosine, picric acid, etc. Salicylic acid cannot be used as the color which it gives with ferric salts interferes, but salicylaldehyde gives the green color. The sensitiveness of the reaction is shown by the fact that the green color is obtained in 1 cc. of a 0.001 *N* soln.

L. W. RIGGS.

Purification of alcoholic extracts obtained from a maceration of putrefying viscera and other organic substances. JORGE MAGNIN AND ENRIQUE V. ZAPPI. *Anales soc. quim. Argentina* 1, 327-36(1913).—M. and Z. propose the following modified Dragendorff procedure for the extn. of alkaloids (free from ptomaines and other possible impurities) from viscera, etc. Macerate the viscera (cut into small pieces) in H₂O slightly acidulated with several drops of H₂SO₄ (1:4), warm (in order to facilitate extn.) for 1-2 hrs. at 40° and allow to stand 18-20 hrs. Filter and add to the filtrate an equal vol. of 90-92% alc., 10 cc. of a 30% Al₂(SO₄)₃ soln. and 10 cc. of a 15% KOH soln.; filter after 2-3 hrs. and conc. *in vacuo* (at a temp. not exceeding 45-50°) to a sirupy consistency. Treat the residue with 20 times its vol. of 90-92% alc., allow to stand 18-20 hrs., filter and again conc. *in vacuo* (as above). Dissolve the residue in H₂O and apply the Dragendorff method for the extn. of alkaloids to the soln. The ptomaines and other impurities are eliminated almost completely by this procedure, while the excess of Al₂(SO₄)₃ causes no inconvenience, inasmuch as it is pptd. by the 2nd alc. treatment. Better results were obtained as the conc. of the alc. was increased, so it is advisable that this conc. be at least 90-92%. The 30% Al₂(SO₄)₃ soln. and the 15% KOH soln. should be employed in the proportions of 10 cc. of each to a vol. of liquid to be purified which is not less than 100-200 cc. Preliminary expts. had shown that no greater purification of exts. of putrefying viscera was effected by reducing agents such as SnCl₂, Na amalgam and powdered Zn in acid media than was obtained by simple filtration. The purifying action of K alum on colloidal suspensions of exts. of putrefying viscera was also negligible. Expts. with activated Al (immersed 3 min. in a 1% HgCl₂ soln. and washed with H₂O until free from HgCl₂) showed that this agent is not as effective in purifying exts. such as the above as is Al₂(OH)₃ produced in the liquid by addition of Al₂(SO₄)₃ and KOH solns. Procedure by the use of activated Al is also slower and requires continuous attention, inasmuch as the acidulated liquid constantly tends to become alk. PhOH, BzOH, picric and salicylic acids, camphor, aconitine, antipyrine, aspidospermine, atropine, berberine, brucine, caffeine, cantharidine, cocaine, colchicine, conicine, convalamarine, curarine, digitalin, digitoxin, helleborine, strychnine, emetine, hydrastine, hydroquinone, morphine, narceine, narcotine, nicotine, papaverine, pelerterine, pilocarpine, piperine, pyrocatechol, quinine, resorcinol, santonin, solanine, theobromine and veratrine were added to the viscera in these expts. All of these substances were detected by means of the purifying procedure 1st described (use of Al₂(SO₄)₃ and KOH), even in cases where the content was no greater than 0.002 g. to 100 g. of viscera, while the use of activated Al caused the complete disappearance of certain substances (picric acid, hydroquinone, resorcinol, solanine, nicotine, etc.) and rendered the reactions with strychnine, morphine, cocaine and quinine considerably less distinct. The usual Dragendorff method (modified by effecting the concs. *in vacuo* as in the Stass-Otto procedure) was compared with the activated Al method of purification, as well as with the previously described method in which Al₂(SO₄)₃ and KOH are used; putrefied beef and beef liver were employed and a number of variations in the procedures were tested. The last named method was found to be preferable in all cases.

8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY.

Johannes Strüver. ARISTIDE ROSATI. *Centr. Min. Geol.* 1915, 321-30.—An obituary notice with portrait and bibliography. E. T. W.

An arrangement of minerals according to their occurrence. E. T. WHERRY AND S. G. GORDON. *Proc. Acad. Nat. Sci. Phila.* 1915, 426-57.—“The types of mineral occurrence are classified on the basis of chem. and geological relations, the chief criterion for subdivision being dissimilarity in mineral content.” In general the term silicic refers to rocks containing more than 45% of SiO_2 , while the terms alkalic, calcic, and magnesian denote that over 7.5% of the oxides suggested by these terms is present. Following is the synopsis of the classification: I. MAGMATIC PHENOMENA.—1. Igneous rocks: A, Silicic (comprising acidic and intermediate, but excluding alkalic, of the usual classifications); B, Alkalic (alkali-syenites and similar rocks); C, Calcic (the basic rocks); D, Magnesian (the ultra basic rocks). Each of the above divisions is subdivided as follows: a, Primary; b, Metamorphosed; c, Weathered. 2. Pegmatites (including pneumatolytic veins and many quartz veins): A, Silicic; B, Alkalic; C, Calcic. Each of the above divisions is subdivided as follows: a, Primary; b, Metamorphosed; c, Weathered. 3. Hydrothermal deposits (the majority of mineral veins, including contact deposits). (No chem. subdivision practicable): a, Primary; b, Metamorphosed (including secondarily enriched); c, Weathered. 4. Fumerolic deposits. (No chem. or historical subdivision practicable.) II. SEDIMENTARY PHENOMENA.—1. Sediments: A, Siliceous (including argillaceous); B, Calcareous (including magnesian); C, Ferruginous (including manganiferous and zinciferous); D, Saline; E, Phosphatic; F, Carbonaceous. Each of the above divisions is subdivided as follows: a, Primary; b, Metamorphosed; c, Weathered. About 800 species of minerals are arranged according to the foregoing classification, and an index given wherein each mineral is referred to its place in the synopsis. L. W. RIGGS.

A list of Canadian mineral occurrences. ROBT. A. A. JOHNSTON. Canada Dept. Mines, *Geol. Survey Mem.* 74, 275 pp. (1915).—A complete list of notable occurrences recorded in Canada up to Dec. 1, 1914. In Part I the list is arranged alphabetically according to names of the minerals; localities are given. In Part II the arrangement is alphabetical according to locality. E. J. C.

Methods of mineral synthesis. J. R. MOURKLO. *Ecole Industrielle, Madrid. Rev. gen. sci.* 26, 394-403 (1915).—Likeness in cryst. form is the most difficult thing to produce in mineral synthesis. Molten anhydrous MnCl_2 is a good solvent for the sulfates of the alk. earths and one is able to obtain, upon cooling its solns. of BaSO_4 , CaSO_4 , or SrSO_4 , crystals resembling barite, gypsum (anhydrite?) or celestite. Synthetic gahnite was obtained by heating Al_2O_3 and ZnO with B_2O_3 in a porcelain oven for 18 hrs. at a red heat. In nature zaraitite and morenosite result from the action of atmospheric gases upon the NiS. Linarite and a similar double sulfate of Cu and Fe are the products of “vitrolization” of the sulfides by atmospheric O. The synthetic re-

production of these is a very simple matter but is much faster than the natural methods and we cannot say that the laboratory methods are the same or even resemble the natural processes. Fluorophosphates or chlorophosphates (wagnerites and apatites) may be made by heating tribasic phosphates with an excess of the corresponding fluoride or chloride in a graphite crucible. We can even substitute the metallic elements and so prep. artificial wagnerites and apatites. Thus, with salts of Ba, Sr, or Pb, apatites are always obtained, while with Mn or Mg salts, wagnerites are the rule. On the other hand, Ca salts yield one or the other according to the working temp. It is also possible to replace the P by As or V or other elements and so obtain well crystd. artificial minerals which are derivatives of wagnerites or apatites. M. obtained the silicate of Ba by heating BaCO_3 and S in a crucible made of a peculiar clay. After cooling slowly, a mass resulted which appeared under the microscope to be isomorphous with wollastonite. Typical apatites, pyromorphite, mimetite, vanadinite, wagnerite, triplite, and analogous products have been produced, seeming to show that nature forms many minerals by simple addition of other chem. combinations. Thenardite is easily obtained by evap. at 33° a soln. of the hydrated sulfate; in nature, it is produced by the efflorescence of mirabilite. M. asserts that the theory of electrolytic dissociation and the electron theory and their extensions to the physical state will change the conceptions of mineral synthesis.

R. L. SIBLEY.

The symmetry of diamond. A. JOHNSEN. Kiel. *Centr. Min. Geol.* 1915, 331-6. —The structure of diamond as detd. by the use of X-rays, especially by W. H. and W. L. Bragg (*C. A.* 8, 599; 9, 1579) is discussed, and the possible space-lattices which will fit this structure considered. It can not be tetrahedral nor tetratohedral, so that the tetrahedral habit sometimes observed must be accidental; certain twins might be regarded as pyritohedral, but the most probable symmetry group is the holohedral. [The work of Fersmann and Goldschmidt (*C. A.* 5, 3789) and of Van der Veen (*C. A.* 7, 1645) is not mentioned.]

E. T. W.

Platinum in the platiniferous chromite of the urals. A. DEL CAMPO Y CERDAN AND S. PIÑA DE RUBIES. Madrid. *Anales soc. españ. fis. quim.* 13, 155-8(1915); cf. *C. A.* 9, 1266. After sepn. of the nuggets of Pt from platiniferous chromite the remaining portion of the latter was tested for Pt. No test for Pt was obtained when 3 or 5 g. chromite was treated in a combustion tube with HCl under pressure. No ppt. was obtained with H_2S after decompn. of 15 g. chromite by Na_2O_3 in a Ni crucible; spectrographic exam. of the filtrate from this liquid failed to show the presence of Pt. Neither could Pt be detected by spectrographic exam. in the material scraped from the wall of the Ni crucible. Pt, if present in platiniferous chromite aside from its localized deposits, must therefore have occurred in an amt. less than would correspond to the limit of solubility of PtS_2 . No ppt. of $(\text{NH}_4)_2\text{PtCl}_6$ could be obtained after treatment of chromite with aqua regia. The mineral itself was thereupon subjected to spectrographic analysis in the ultraviolet region. Pt was detected in appreciable amt. in each of the 4 samples of chromite which were tested. The principal characteristic rays which were observed corresponded to λ (Å. u.) 3064.82, 2998.07, 2928.90, 2830.40, 2705.99, 2702.50 and 2659.60. These results indicate that Pt occurs in minute amt. in a uniformly, finely divided condition throughout the mass of chromite, as well as in the localized deposits or nuggets.

H. S. PAINE.

Salt from Somaliland. ANON. *Bull. Imp. Inst.* 13, 190-2(1915).—The salt examd. was found to be very similar in compn. to most rock salts, except that it often contained small amts. of NaHCO_3 (0.3%). If the salt is dissolved in $2\frac{1}{2}$ times its weight of water, allowed to stand and the clear liquid decanted off and allowed to crystallize at 40° until about 80% of the total quantity is recovered, a refined salt free from

NaHCO_3 is obtained. This refined salt is of a good color and does not deliquesce upon exposure to the air.

R. L. SIBLEY.

Is lublinitite a new monoclinic modification of calcium carbonate? RICHARD LANG. *Centr. Min. Geol.* 1915, 298-305. A reply to Mügge (*C. A.* 9, 576).—L. verboosely restates the grounds on which he bases his conclusion that lublinitite is distinct from calcite. The principal proof appears to be that it gives different staining tests than the latter. It is also suggested that the material examd. by M. was not normal lublinitite, but a calcite pseudomorph after it.

Chemical analysis of the mineral prehnite. BERTHAULT DE ST. JEAN VAN DER RIET. *S. African J. Sci.* 11, 300-1 (1915).—Analyses of 3 specimens of prehnite from Cape Town gave the following results: SiO_2 43.51-44.43, Al_2O_3 23.50-25.79, Fe_2O_3 none-1.91, CaO 24.12-26.03, FeO 0.25-0.89, Na_2O none-0.36, H_2O 4.27-5.05.

J. H. BOWER.

Occurrence of radioactive minerals in Ontario. S. BRUNTON. *Summary Rept. Geol. Survey, Dept. Mines Canada* 1914, 91-4.—A report of an investigation of waste dumps, concentrates from ore-dressing plants and of all minerals which seemed at all likely to show radioactivity. These were all tested with the most delicate instruments possible to be transported from place to place. In only 2 localities were traces of such minerals found; a small deposit of columbite and another resembling samarskite.

R. L. SIBLEY.

Radioactive minerals in eastern Canada. C. W. ROBINSON. *Summary Rept. Geol. Survey, Dept. Mines Canada* 1914, 109-12.—A report of the investigation of localities where radioactive minerals had been reported to occur. Specimens were examd. in the field with the scintilloscope but no deposits of radium-bearing minerals were found.

R. L. SIBLEY.

Monazite. TIPPER. *Rec. Geol. Surv. India* 44, 186; *Bull. Imp. Inst.* 13, 323-4 (1915).—The occurrence of monazite in 5 localities is reported. The monazite occurs in the pegmatite intrusions that traverse the gneisses and shows 6% thorium. No monazite was found in the gneisses although it is supposed to have been derived primarily from the disintegration of these rocks.

R. L. SIBLEY.

Composition of pyromorphites. M. AMADORI AND E. VITERBI. *Mem. Accad. Lincei* 10, 386-408 (1914); *J. Chem. Soc.* 108, II, 358-9.—Twenty specimens of pyromorphite of diverse origins have been analyzed. The sp. gr. varies only between 7.06 and 7.12, these limits being far closer than those given by Dana ("System of Mineralogy," 6th Ed., 770), namely, 6.5 and 7.1. The greater or less proportion of arsenate occurring in the pyromorphite does not alter the sp. gr. sensibly, the values for the chloroarsenate mimetite being 7.0-7.25, and the content of Ca is too small to produce appreciable variation. Most of the specimens examd. contain As and all show the presence of Ca, but the proportions of the latter element found are probably higher than those really present, owing to the protracted manipulations necessarily preceding the estn. The value of the ratio, $\text{RO}_4:\text{Cl}$, varies between 2.95 and 3.04, the small deviations from the value 3 being due, undoubtedly, to exptl. error in the estns. Thus, all the specimens examd. have the comp. $\text{MCl}_2.3\text{M}_2(\text{PO}_4)_4$, and the divergent results obtained by previous investigators appear to result from imperfect analytical methods or from faulty prepn. of the material analyzed; the low values often given for the % of Cl are probably caused by soln. of the mineral in the warm. Pyromorphites of slightly diff. comp. may occur in one and the same locality, and variations are also found between the comps. of the outer and inner layers of a single crystal. With 2 specimens from Wheal Alfred, in one case the inner, and in the other the outer portions contd. the more As.

E. J. C.

Researches on the chemical and mineralogical composition of meteorites. GEORGE P. MERRILL. U. S. National Museum. *Proc. Nat. Acad.* 1, 429-31(1915).—Upwards of 20 meteorites have been subjected to searching chem. analyses; in none of them could Sb, As, Au, Pb, Sn, W, U, Zn, Ba, Sr or Zr be detected, but the presence of traces of Pt, Pd, Ir, Ru, and V was proved. The Pt metals are present in the metallic portions as is also the V; the Ni and Co occur in both metallic and silicate minerals. The form of the P in the silicates and the presence of CaS has been previously described (*C. A.* 9, 2208). A table is given showing the av. comp. of 53 stony meteorites (some constituents detd. in only a few of the analyses) compared with the comp. of the earth's lithosphere (Clarke), and with previous averages of the comps. of meteorites by M. and Farrington. The av. comp. of the meteorites is: SiO₂ 38.68, TiO₂ 0.18, SnO₂ none, ZrO₂ none, Al₂O₃ 2.88, Cr₂O₃ 0.47, V₂O₅ trace, Fe 11.98, Ni 1.15, Co 0.07, FeO 14.58, NiO 0.48, CoO 0.06, CaO 2.42, SrO none, BaO none, MgO 22.67, MnO 0.29, Na₂O 0.87, K₂O 0.21, Li₂O trace, H₂O 0.75, P₂O₅ 0.26, S 1.80, Cu 0.014, C 0.15, Cl 0.08, F(?), CO₂(?), sum 100.044%.

E. T. W.

Gay Gulch and Skookum meteorites. R. A. A. JOHNSTON. *Canada Dept. Mines, Geol. Survey, Museum Bull.* No. 15, 8 pp.(1915).—Two meteorites discovered in the Yukon region are described. The first (sp. gr. 7.566), contained: 83.85% Fe and 15.03% Ni; the second (sp. gr. 7.561) 80.65% Fe and 18.2% Ni. When a section of each was polished, there appeared a thin zigzag streak of a silver-white substance with a metallic luster of unknown identity. Both showed crystallographic arrangement which seemed to indicate that they formed a part of the same shower.

R. L. SIBLEY.

Some recent mineral discoveries in Namaqualand. W. VERSFELD. *S. African J. Sci.* 11, 350-3(1915).—Minerals of commercial importance which have recently been discovered are tantalite, columbite, Bi ores, Li compds., Mn ores, corundum, graphite, fluorspar, molybdenite, alum, rock salt, gypsum, and Fe ores.

J. H. B.

The geology of the iron-ore deposits in and near Daiquiri, Cuba. JAMES F. KEMP. *Bull. Am. Inst. Mining Eng.* 1915, 1801-36.—The oldest rock of the region in question, which lies east of Santiago, is a dense blue limestone resembling the Appalachian Cambrian and Ordovician, cut into irregular exposures by the intrusion of a quartz-diorite or granite. This granite is itself cut by dikes of diorite which are believed to be the supply conduits for the large masses of diorite which contain the ore. The ore is mainly a fine grained cellular magnetite with quartz, garnet, and pyrite filling the interstices, whose texture is most easily explained as due to replacement of diorite. K. suggests that while the diorite mass was still hot in the depths a pronounced N. W. and S. E. fissured zone was formed up through which came fluid or gaseous emissions bringing Fe for the ore, the FeS₂ and the garnet, S for the FeS₂, and SiO₂ for the quartz and garnet. The Fe probably came up as a chloride. In ores from mines above the water-level pyrite has been oxidized but in deeper works it is unaltered. In small workings, limits of 50% Fe and 12% SiO₂ were maintained but operations have now been abandoned.

H. L. OLIN.

The formation of the oxidized ores of zinc from the sulfide. YINCHANG T. WANG. *Bull. Am. Inst. Mining Eng.* 1915, 1959-2012.—From a study of the formation of the 3 minerals calamine (Zn(OH)₂.ZnSiO₃), smithsonite (ZnCO₃) and hydrozincite (ZnCO₃.2Zn(OH)₂) from ZnS, using solns. of a group of substances capable of dissolving the blende or of converting its oxidation product into a carbonate or basic silicate, W. draws the following conclusions: sphalerite (ZnS) is first attacked by the oxidation products of FeS₂ before the formation of the secondary minerals containing Zn; rarely are the oxidized ores formed by direct replacement of ZnS. Smithsonite is formed by solns. of bicarbonates, and hydrozincite by solns. of normal carbonates. Lime-

stones may be replaced in nature by solas. of a Zn salt, usually the sulfate, as well as by smithsonite and calamine. Silicates of Zn cannot exist in the presence of free CO_2 . Calamine in nature is probably formed by steps, being pptd. from waters containing ions of a gelatinous silicate and of hydroxide but time is an important factor in the process. Minute crystals of calamine were formed by heating to 900° a mixt. of 1 part H_2SiO_4 and 30 pts. of 1 equiv. Na_2SO_4 and 0.5 equiv. ZnSO_4 .

H. L. OLIN.

Conditions of black shale deposition as illustrated by the Kupferschiefer and Lias of Germany. CHARLES SCHUCHERT. Yale Univ. *Proc. Am. Phil. Soc.* 54, 259-69(1915).—A study of the biologic, geologic, and chem. conditions accompanying the formation of the Kupferschiefer, and in the Black and other seas, show that foul bottoms are due to a lack of H_2O circulation, either because of no wide connection with oceanic areas, or because of inadequate vertical convection currents. Under these conditions the O is consumed by the organisms at or near the surface leaving the depths stale and lifeless. As the sulfur bacteria, which are always present, thrive best in the stale bottoms, they accumulate, yielding an ever increasing amt. of H_2S , provided they are furnished with dead organisms on which to feed. The sunlit, aerated upper layers of water support green plants, which after death sink. Depth of water is not essential to the formation of foul bottoms, except that large areas must have depths exceeding 300 ft., otherwise wave action would set up sufficient vertical currents to replenish O and remove the foul gases of the lesser depths.

L. W. RIGGS.

Notes on black shale in the making. W. N. TWENHOFEL. Lawrence, Kansas. *Am. J. Sci.* 40, 272-80(1915); cf. preceding abstr.—T. gives a review and criticism of the opinions of other workers, and from a study of the sulfurous littoral black muds in the Baltic Sea and other localities, as well as the black shales of Kansas and Canada, considers it absolutely certain that black hydrocarbonaceous shale may form in water so shallow that it is but a step to land conditions.

L. W. RIGGS.

Concretions in streams formed by the agency of blue-green algae and related plants. H. JUSTIN RODDY. Millersville, Pa. *Proc. Am. Phil. Soc.* 54, 246-58(1915).—The occurrence of calcareous concretions in streams and their flood plain deposits at several points is described. Their approximate comp. is: growing specimens, CaCO_3 60-75, MgCO_3 trace-1, SiO_2 12, Al trace, Fe 1, H_2O 1 and organic matter 10-15%; from flood plain deposits: CaCO_3 70-80, MgCO_3 trace-1, SiO_2 12, Al trace, Fe 2, H_2O 1, and organic matter 1-12%. Microscopic exam. shows the presence of several types of algae, and the concentric laminated structure is evidently due to growth during the summer seasons, and its cessation during the winters. The occurrence of such algal deposits in other regions and in past geological periods is discussed. It is shown by a table of the salinity of several streams that the concretions only form when the salinity exceeds 200 parts of $\text{CaH}_2(\text{CO}_3)_2$ per million.

E. T. W.

A discrepancy in geochemical data. H. S. SHELTON. *Chem. News* 112, 85-8 (1915); cf. *C. A.* 5, 850; 9, 677.—S. again asserts his belief that there must be an error in S detn. in H_2O because of the discrepancy between the amts. of S found in rivers and in the ocean. He replies to the discussion of the subject by Dole (*C. A.* 9, 1209) but without adding any new data. He fails to find the activities of man in opening mines, etc., and thereby bringing S compds. into the range of erosion sufficient explanation of the high S content of rivers.

The outlook for iron. J. F. KEMP. *Trans. Intern. Eng. Congress 1915* (advance copy), 25 pp.—A review including statistics and a bibliography. F. W. S.

Coarse crushing plant; 1,000 tons capacity. G. O. BRADLEY. *Trans. Intern. Eng. Congress 1915* (advance copy), 8 pp.—B. describes with plates a proposed arrangement of coarse crushing equipment for 1,000 ton plant. A table is given showing type of crusher recommended for a given ore. F. W. SMITHER.

Advances made in the metallurgy of copper, Globe District, Arizona. L. O. HOWARD. *Trans. Intern. Eng. Congress 1915* (advance copy), 3 pp.—A brief review. The greatest advance has been in the successful attempt to work the low-grade porphyry deposits of the Miami and Inspiration properties. F. W. SMITHER.

The place of copper in the present engineering field. H. D. HAWKS AND T. T. READ. *Trans. Intern. Eng. Congress 1915* (advance copy), 27 pp.—A discussion of the uses of Cu. The elec. industry at the present time consumes between 60 and 70% of all the new Cu produced. E. J. C.

The development of zinc smelting in the United States. GHO. C. STONE. *Trans. Intern. Eng. Congress 1915* (advance copy), 29 pp.—A discussion and review with production statistics included.
E. J. C.

Some main points in the economics of the metallurgy of zinc. W. R. INGALLS. *Trans. Intern. Eng. Congress 1915* (advance copy), 11 pp.
E. J. C.

Vanadium. ANON. *Engineering* 100, 170(1915).—A brief review of the occurrence, properties, uses, etc., of V.
F. W. SMITHER.

Wet method of mercury extraction. C. A. MULHOLLAND. *Mining Sci. Press* 111, 346(1915).—Discussion of a paper by Thornhill (cf. *C. A.* 9, 1891), especially of the chem. reactions involved.
F. W. SMITHER.

Manganiferous iron ores of the Cuyuna range. EDWARD P. McCARTY. *Univ. Minn. Eng. Mining J.* 100, 400-2(1915).—Av. analyses of various types of these ores are given. There is in general too much P present for the ores to be of wide application and it is in such a form that it cannot be satisfactorily sepd. magnetically, or by any other single mechanical process.
E. T. WHERRY.

Rotary kilns for desulfurization and agglomeration. S. E. DOAK. *Bull. Am. Inst. Mining Eng.* 1915, 2061-6.—A discussion of the utilization of rotary kilns, of the cement type, for the desulfurization and agglomeration of pyrites cinder to be used as a large part of the blast-furnace burden. The one great obstacle now in the way of continuous operation is the formation of "rings," caused by the cinder becoming hot enough to stick to the lining. It is in localities where the native ore is lean that the kiln is valuable, affording an opportunity of enriching the burden with a high grade ore at a much lower cost than could be done by direct purchase of lake or other rich ores, and where the SiO_2 in the native ore averages well over 20%.
F. W. SMITHER.

Surface-flow phenomena. J. E. HURST. *Engineering* 100, 130-1(1915), illus.—Engineers know that the best running properties of internal-combustion engine cylinders, slide-valve guides, bearings, etc., may be expected after the parts have been in use for a certain time and a hard glazed surface has resulted. This is probably a result of surface flow of the vitreous or amorphous phase of the metal. The original microscopic structure of the metal is noticeably changed as a result of such flow and tool marks are obliterated to some extent. A number of practical examples are cited.
WILLIAM T. HALL.

A modified iron-carbon diagram. EDWIN A. SPERRY. *Pei Yang Univ., Tientsin. Met. Chem. Eng.* 13, 469-71(1915).—To reconcile somewhat conflicting statements in text books a compromise diagram is drawn for the use of Chinese students. Such a diagram has no exptl. justification.
W. T. HALL.

The diffusion of carbon in iron. F. W. ADAMS. *Engineering* 100, 95-7(1915), illus.—Royston has shown that when a hard steel in close contact with a mild steel is heated in a vacuum at 900° diffusion of C takes place from the former into the latter but some doubt exists as to whether C diffuses as such or as Fe_3C . The confirmatory results now obtained show that such diffusion takes place but only when the surfaces of the two metals are in very close contact. When in sufficiently close contact, welding and intercrystallization takes place between the specimens and the extent of the welding is not influenced by the C content of either sample; after such welding has taken place the transference of the C is much more rapid than is ordinarily accomplished by cementation by means of CO. When a white Fe was heated with a mild steel considerable migration of the C took place but as there was no evidence of graphitization the results would apparently indicate that the migration was of Fe_3C rather than of free C. Samples of iron and steel are likely to lose wt. when heated in a vacuum; apparently some Fe and some C is volatilized.
WILLIAM T. HALL.

Can the dissociation theory be applied to solid solutions in steels? E. D. CAMPBELL. *J. Am. Chem. Soc.* 37, 2039-46(1915).—Specimens were heated to 892°, quenched and reheated to various temps. from 20° to 800°. Samples were analyzed after each treatment. As the temp. of reheating increased, the amt. of dinitro compds. derived from carbides sol. in cold HNO₃ decreased somewhat regularly; the amt. derived from carbides insol. in cold acid but sol. at boiling temp. increased from 12.8 at 20° to 39.0 (arbitrary units) at 800°. The sp. elec. resistance closely paralleled the decrease in color from carbides sol. in cold HNO₃, i. e., the concn. of carbide. The "molar concn." of C, P, Si, and S in the steel has been calcd., assuming steel to weigh 7800 g. per l. If the products of dissociation of a solute (called "ionoids") in a solvent of high sp. cond. be assumed to resemble the ions of electrolytic dissociation in its usual form, the theory would be just as applicable to solid solns. in metals as to aq. solns., although the phenomena, when the 2 solns. were subjected to a difference of potential at 2 points, would manifest themselves in opposite directions. The differences are due mainly to the differences in elec. properties of the solvents. E. B. MILLARD.

Radiography of metals. WHEELER P. DAVY. *Bull. Am. Inst. Mining Eng.* 1915, 1515-26; *Gen. Elec. Rev.* 18, 795-800(1915), illus.—The presence of blow-holes, slag inclusions, porous spots and the general gross structure (not the grain) can be detd. by taking an X-ray picture, provided the metal is not too thick. Thus holes purposely drilled could be detected in boiler plate and air inclusions 0.52 mm. thick were noticeable in steel which was 31.3 mm. thick. There is no other method of obtaining such information which does not involve cutting the sample. The method of carrying out the tests is described and the proper voltages to use are given. WILLIAM T. HALL.

The commercial production of sound, homogeneous steel ingots and blooms, EMIL GATHMANN. *Bull. Am. Inst. Mining Eng.* 1915, 1485-92, illus.—To produce a sound *piping* steel free from blow-holes, a mold has been devised which has thinner walls at the top than in the middle and bottom sections and is provided with a sink head which is made of poor heat-conducting material. Good ingots can be prepared with such a mold even although, to save expense, the big end is down; the discard can be reduced to about 10%. Early stripping and rolling will reduce the pipe. In blooming the ingots, the rolling should begin while the interior is still hotter and more plastic than the exterior but the ingot must remain in the soaking pit until the steel is entirely set. The best method of reducing the ingot is in *but-to-end* passes. W. T. HALL.

Some suggestions regarding the determination of the properties of steel. A. N. MITINSKY. *Bull. Am. Inst. Mining Eng.* 1915, 1697-706.—The *proportional limit*, i. e., the point at which the extensions cease to be proportional to the loads in tensile strength tests, is recommended as the proper basis of all engineering calculations. This limit is independent of the yield point and of the ultimate strength. It should be as high as possible for metals which are to be subjected to repeated loads, shocks, wear by crushing, etc. Such wear of metals is practically independent of the ultimate strength, yield point and Brinell number. Wear by flow of metal or by crushing depends only on the proportional limit. Factors affecting wear by abrasion were not detd. completely but the deleterious influence of S was noted. It is impossible to destroy a metal by any number of repeated stresses if the proportional limit is not exceeded by the individual stresses, and fatigue is found only when this limit has been exceeded. WILLIAM T. HALL.

The properties of cold-worked metals. I. The density of metallic filings. THOMAS M. LOWRY AND REGINALD G. PARKER. *J. Chem. Soc.* 107, 1005-18(1915).—The changes in d. produced by filing and then by annealing at different temps. were studied with Mg, Al, Sb, Zn, Sn, Fe, Cd, Co, Ni, Cu, Bi, Ag, Pb, Pd, Au and Pt. In

general, the d. of the worked metal was found less than that of the metal as purchased and, conversely, complete annealing is always accompanied by a contraction. This contraction, in the light of Beilby's theory, is due to the recrystn. of the amorphous material which is produced by work on the metal. The contraction, however, is preceded by an expansion. In the case of Au, Ag, Cu, Co, Ni and Sb the intermediate expansion is preceded by a preliminary contraction which is apparently a specific property of a limited number of metals. In the case of Au, the preliminary contraction and the intermediate expansion can be observed to take place consecutively when the metal is heated at 100°. The process of annealing, therefore, may involve 3 distinct changes, of which only the last has been explained satisfactorily. Probably an allotropic change is the cause of the preliminary contraction and the release of mechanical strain of the intermediate expansion.

WILLIAM T. HALL.

Corrosion of iron and steel pipe. W. A. DUNKLEY AND J. E. NOBLE. *Power* 41, 584-5 (1915).—Comparative phys. and chem. tests of steel and wrought Fe pipes apparently show the former to be superior. Cf. C. O. Standstrom, *Ibid* 41, 416.

W. H. BOYNTON.

Corrosion of metal flume sheets. I. C. HARRIS. *J. Elec. Power & Gas* 34, 542 (1915).—An investigation of rustless, "pure" and "Cu-bearing" irons and corrosion-protecting coatings has been made by the Reclamation Service with the result that "it appears that there is no justification for the payment of a higher price for one material than for another on the basis of non-corrodibility when used under the usual conditions encountered on the projects of the Reclamation Service."

W. E. R.

External corrosion of cast iron pipe. MARSHALL R. PUGH. *Chem. Eng.* 22, 47-54 (1915); *Am. Gas Light J.* 103, 65-70 (1915).—Ordinarily, cast Fe pipe embedded in soil will last for from 1 to 3 centuries but in salt marshes or in other saline soils its life may be only 7 yrs. Slag and cinder fills are deleterious and acid mine waters are destructive. Substituting wrought-Fe or steel pipe is ineffectual. To prevent corrosion, (1) the skin resistance may be increased, (2) the pipe may be embedded in lime or cement, (3) acids, salt and air may be excluded, or (4) the pipe may be galvanized.

WILLIAM T. HALL.

Researches on the iron, silicon and carbon alloys. GEORGES CHARPY AND ANDRÉ CORNU-THENARD. *Engineering* 100, 173-7 (1915), illus.; cf. C. A. 8, 484, 2999.—When the % Si rises, the A₂ point rapidly becomes less pronounced and rises slightly on the temp. scale. The H point rises with % Si, passes A₂ and gradually becomes fainter in character and finally disappears when all the C exists as graphite. The A₂ point falls gradually when % Si rises, becomes less and less intense, but can be detected up to 7% Si and is then the only one of these 3 points that remains. Every increase in Si lessens the soln. of C in Fe. The influence of Si on the rate of graphite pptn. is so great that in certain irons the graphite pptn. gives rise to a thermal point.

WILLIAM T. HALL.

A bearing metal of high elastic limit. ANON. *Iron Age* 95, 1016 (1915).—Alloy "Noheet" contains 97% Pb hardened with an alkaline substance. It is much stronger than Babbitt metal.

H. V. MAIN.

One of the causes that may give rise to internal lacerations in steel ingots of large dimensions. F. GIOLITTI. *L'industria* 29, 243, 263 (1915); through *Ann. chim. applicata* 3, 376-7 (1915).—Solus. of continuity that often appear in large steel ingots may be attributed either to chem., physical or unknown causes. G. studied a laceration in a large Ni-steel ingot, the contiguous surfaces differing in macro- and micro-structure and in chem. comp. In 1 of the 2 parts the concn. of C, P and Mn was greater than in the other. This might indicate the formation of abnormal or parasitic germs

of crystn., producing liquation phenomena and inducing the non-homogeneity of the ingot and soln. of continuity. G. suggests considerations looking to the avoidance of inconveniences of this kind. S. LEVY.

Metallographic grinding and polishing machine. ANON. *Iron Age* 95, 1164 (1915).—This combined machine, designed by Wysor, of Lafayette College, is sold by Eimer & Amend. H. V. MAIN.

Vanadium from oxide to steel. W. F. BLEECKER AND W. L. MORRISON. *Met. Chem. Eng.* 13, 492-4 (1915).—The manuf. of Fe-V and its uses are discussed in detail. It may be prepared from oxide by the thermit process, by reduction in the elec. furnace with Al or in the same way with Si as reducing agent. The efficiency of these different methods is discussed. Instead of using Fe-V in the preparation of V-steel, $\text{Ca}_2(\text{VO}_4)_2$ mixed with a little Fe scale and an excess of Si or of Al may be added to molten steel directly. To get the best results with such a mixt. it should be added to the charge in an elec. furnace just before pouring into the ladle. The resulting steel usually contains 0.08 to 0.38% V and it is produced more economically than when Fe-V is used. F. W. SMITHER.

The engineering uses of aluminium. JOS. W. RICHARDS. *Trans. Intern. Eng. Congress 1915* (advance copy), 17 pp.—A discussion of the phys. and chem. properties of Al and the uses based thereon. Light but strong Al alloys are also discussed. E. J. C.

99.84 percent. pure iron for electrical purposes. ANON. *Elec. World* 66, 213 (1915).—"Armco" iron is made in the basic open-hearth furnace by a special process which eliminates as far as possible all solid and gaseous impurities. A guaranteed analysis of Si 0.002, S 0.02, P 0.005, C 0.1, Mn 0.02, and Cu 0.03% is given. Oxidation tests made on charcoal iron, steel and "Armco" by immersing in alk. H_2O for 3 yrs. showed the steel to be badly pitted, with a loss of 9 oz. per sq. ft. surface. The charcoal iron and "Armco" were both uniformly corroded and lost 14 oz. and 7 oz. per sq. ft., resp. Armco Fe rusts, but the oxide formed is finer and more adherent and protects the metal against deep corrosion. A high permeability and low residual magnetism make the product useful for solenoids, etc., while its corrosion-resisting properties makes it desirable for transmission towers, anchor rods, outlet boxes, etc. Photomicrographs of puddled iron, mold steel and "Armco" are given. W. E. RUDER.

Allotropy and metastability of metals (HOLT) 2.

U. S., 1,150,897, Aug. 24. A. C. SPENCER. Recovering residual zinc minerals from calcareous final tailings from ores such as franklinite or willemite. The tailings are passed through a calcining zone against a current of oxidizing flame and gases at a temp. sufficiently high to over-burn the CaO produced. The lime is then sepd. from the heavy mineral constituents of the calcined mixt. by gravity sepn. on a concentrating table.

U. S., 1,151,049, Aug. 24. C. H. A. F. L. ROSS. Steel bars, etc., are toughened by immersing in a bath of molten metal at a temp. of about 780° while supplying to the bath for a period under 10 min. over 125 B. t. u. per min. for each lb. of steel, then quenching the steel at 65° or below in a bath of NH_4Cl , alum and NaCl , reheating to about 540° and quenching again at 50° or below after heating for 8 min.

Separating iron and nickel from copper in sulfide ores, mat, etc. The material is smelted with an excess of lime flux and just sufficient C to reduce the Ni and Fe and gradual reduction is effected by heating. The CaS present retards the sepn. of Cu and an Fe-Ni alloy is obtained which is nearly free from Cu. Cf. C. A. 8, 2337.

U. S., 1,152,959, Sept. 7. A. W. MACHLEY. Case-hardening iron or steel by exposure while heated to an atm. of CO and NH₃ charged with naphtha vapor.

Brit., 9,776, Apr. 20, 1914. F. WERNER. In welding steel or cast-iron, the uniting metal and the surfaces to be welded are heated to a condition of plasticity and then welded by hammers with rounded faces, the uniting metal being inserted at intervals. In welding fractures in boiler plates, etc., *in situ*, the plate is bevelled and bent at the fractured edges so that expansion of the plates does not affect the strength of the joint and the cavity is gradually filled in layers with metal by heating an Fe rod to a condition of plasticity by means of an oxy-acetylene, oxy-hydrogen, or like burner. The layers are compressed by a hammer having a spherical end to avoid the presence of cavities in the weld or stretching of the metal at the weld. Further layers are then applied, and similar hammers of gradually increasing size utilized for completing the joint. The joint is heated after welding, and a magnet used to test whether it is demagnetized. A profiled joint may be made by forging during the welding operation.

Brit., 9,939, July 4, 1914. R. WRIGHT and J. CALDERWOOD. In a blast furnace in which the fuel is introduced by sep. shafts arranged around the central ore and flux shaft, the fuel is admitted above the combustion zone undecomposed and relatively cool.

Brit., 10,312, Apr. 25, 1914. L. A. WOOD and MINERALS SEPARATION, LTD. Concentrating ores, such as sulfide ores, by subjecting a pulp free from oil or frothing agent to the admission of a gas, the bubbles of which raise certain particles of the ore towards the surface and discharge them within the pulp, below the surface of which they are caught and removed. The pulp may be acidified.

Brit., 10,500, Apr. 28, 1914. E. R. WEIDLEIN. A process of extracting copper. See U. S., 1,089,096 (C. A. 8, 1409).

Brit., 10,582, Apr. 29, 1914. B. TALBOT. An anti-corrosive alloy is made by piling rolled sheets of Fe or steel containing 0.3 to 3% Cu, and then heating and hammering or rolling the pile. The sheets at 1 or both surfaces may contain more Cu than the others; or the % may be graduated, decreasing from the surface to the center of the pile.

Brit., 10,598, Apr. 29, 1914. N. E. MACCALLUM. In an open-hearth furnace for the manuf. of steel, the roof, hearth, side and end walls or linings, the walls or arches sepg. the air and gas ports, the doors, and any other wall or portion thereof exposed to the chem. reactions and high temp. of the furnace, are built up of tubular metal containers filled with basic material, such as dolomite, magnesite, and lime, or with neutral material, such as chromite, bauxite, and C, or with a mixt. of such basic and neutral materials.

Brit., 10,630, Apr. 30, 1914. N. S. BRAYSHAW and E. R. BRAYSHAW. In a gas-fired annealing furnace of the kind provided with burner openings arranged beneath the hearth, swivelling gas burners are provided adapted to be withdrawn from the openings in the furnace bottom, the openings being then closed by dampers; also longitudinal scale, slag, or dirt collecting passages may be arranged at the sides of the hearth.

Brit., 10,872, May 2, 1914. GEN. ELEC. CO. Bearings or wearing surfaces of ferrous metal are coated with Zn or other metal by sherardizing. A cast-Fe bearing

is first annealed at a bright red heat to prevent subsequent distortion, and is then heated at a dull red heat for 3-4 hrs. or more in a closed revolving box or cylinder containing Zn dust. After cooling, the bearing may be reamed out to the correct size. The invention is applicable also to shafts, journal boxes, cylinders, pistons, piston-rings, and other wearing surfaces of relatively moving parts.

Ger., 283,035, Feb. 6, 1913. H. BROSCHE. A coating for metal cores, for use in casting tubes and the like from metals such as cast Fe, brass, bronze, and the like, consisting, besides a suitable binder, of a substance such as $MgSiO_3$, which does not fuse or burn at the pouring temp., and which acts as a lubricant after pouring, permitting the easy withdrawal of the solidified casting. Guido Goldschmiedt. RUD. WEGSCHNEIDER. *Chem. Ztg.* 39, 649-50(1915).—An obituary. J. H. MOORE.

Acenaphthylene and its derivatives. BERTRAM CAMPBELL. Imperial Coll. Sci. Tech., London. *J. Chem. Soc.* 107, 918-21(1915).—Acenaphthylene (A), yellow plates, m. 93°, prepd. by Dziewonski and Rapalski's method (C. A. 7, 89), was freed from acenaphthene by fractional crystn. of the picrates. (A) in CCl_4 when treated with an equimol. amt. of Cl yielded 1,2-dichloroacenaphthene (I), glistening plates

from petroleum, needles from alc., m. 115° , which on oxidation with KMnO_4 yielded naphthalic acid. When heated in EtOH with EtONa (I) formed 1-chloroacenaaphthylene (II), yellow oil. I in Et_2O acting upon an equimol. amt. of (A) in Et_2O yielded a pale yellow powder containing no I and having properties similar to those of "polyacenaaphthylene" described by D. and Leyko (cf. C. A. 8, 2729). LOUIS E. WISE.

Alcoholysis. I. Dilatometric determinations of the velocity of alcoholysis in the presence of a large amount of alcohol. GOPAL B. KOLHATKAR. Indian Inst. Sci., Bangalore. *J. Chem. Soc.* 107, 921-33(1915).—K. has detd. the velocity of alcoholysis in alc.-ester mixts., in the presence of HCl, by the dilatometric method. In a series of preliminary expts., K. showed that in the absence of a catalyst, the ester-alc. mixts. showed no appreciable changes in vol. after long standing; that the variation in concn. of the reacting substances is a linear function of the change in density of the reacting substances; that the catalyst had a negligible effect on the vol. of esters alone, but a slight though appreciable effect on the vols. of the alcs. alone, for which suitable correction was made in the later expts. A set of expts. further indicated that the alcoholysis velocity const. increased in proportion to the increase in HCl concn. Measurements were carried out as follows: The ester was mixed with 20 molar proportions of the requisite alc. previously treated with sufficient HCl gas to form an approx. 0.02 *N* HCl soln. The dilatometer, 50-70 cc. capacity with only 1 capillary (internal diameter about 0.8 mm. and length between the bulb and the tap of the dilatometer 30-40 cm.), was almost completely filled with the above mixt. at about 20° and then transferred to an electrically heated bath kept constantly at 30° ($\pm 0.01^{\circ}$), smaller temp. variations being recorded by a Beckmann thermometer and vol. corrections applied. The level of the liquid in the dilatometer capillary was then adjusted to a convenient height, and readings of the level of the meniscus taken at convenient intervals by means of a reading microscope, until the vol. remained nearly const. In general the system reached equil. when 96% of the ester had been transformed. In all cases the const., k , was computed by the use of the equation $k = 2.3026(1/t \cdot \log a/(a - x))$ where a is proportional to the initial concn. of ester and x to the amt. of ester changed in t mins. The mean values of k were invariably corrected for 0.02 *N* HCl. The following list gives the mixts. and the corr. values for k in parentheses: $\text{AcOEt} + \text{MeOH}$ (0.00608); $\text{AcOPr} + \text{MeOH}$ (0.00546); $\text{iso-PrOAc} + \text{MeOH}$ (0.00214); $\text{iso-BuOAc} + \text{MeOH}$ (0.00488); $\text{iso-AmOAc} + \text{MeOH}$ (0.00495); $\text{iso-BuO}_2\text{CH} + \text{MeOH}$ (0.218); $\text{EtCO}_2\text{Et} + \text{MeOH}$ (0.00375); $\text{PrCO}_2\text{Et} + \text{MeOH}$ (0.00204); $\text{CCl}_3\text{CO}_2\text{Et} + \text{MeOH}$ (0.000229); $\text{CH}_2\text{ClCO}_2\text{Et} + \text{MeOH}$ (0.00249); $\text{BzOEt} + \text{MeOH}$ (0.0000371); $\text{AcOMe} + \text{EtOH}$ (0.00172); $\text{AcOMe} + \text{PrOH}$ (0.00105); $\text{AcOMe} + \text{iso-PrOH}$ (0.000723); $\text{AcOMe} + \text{iso-BuOH}$ (0.000776); $\text{AcOMe} + \text{iso-AmOH}$ (0.000861); $\text{EtCO}_2\text{Me} + \text{EtOH}$ (0.000979); $\text{PrCO}_2\text{Me} + \text{EtOH}$ (0.000546); $\text{CH}_2\text{ClCO}_2\text{Me} + \text{EtOH}$ (0.000953). The rates of esterification of acids by the catalytic method (cf. Sudborough and Gittins, *J. Chem. Soc.* 93, 211(1908)) and of the alcoholysis of the corresponding esters by HCl follow the same order: $\text{HCO}_2\text{H} > \text{AcOH} > \text{EtCO}_2\text{H} > \text{PrCO}_2\text{H} > \text{CCl}_3\text{CO}_2\text{H} > \text{BzOH}$ (the sole exception being $\text{CH}_2\text{ClCO}_2\text{H}$). The relative activities of alkyl groups calcd. from the acetate alcoholysis expts. and taking Me as 100 are $\text{Et} = 28$; $\text{Pr} = 19$; $\text{iso-Pr} = 3.4$; $\text{iso-Bu} = 16$; $\text{iso-Am} = 17$. The ratios $(\text{Et ester} + \text{MeOH})/(\text{Me ester} + \text{EtOH})$ are very nearly identical for acetates, propionates and butyrates, being 3.5, 3.8, and 3.7, resp. This indicates that the relative affinities of Me and Et groups towards an acyl group are to some extent independent of the nature of that group. LOUIS E. WISE.

Synthesis of benzo- γ -pyrones and flavones. II, III. SERGE JACOBSON AND BROJENDRANATH GHOSH. Univ. Coll., London. *J. Chem. Soc.* 107, 959-66, 1051-8 (1915).—(Throughout this article J. and G. use the term "Et β -benzoyl- α -

phenylpropionate," to which they assign the enolic formula: $\text{HOCPh:C}(\text{C}_6\text{H}_5)\text{-CO}_2\text{Et}$. Judging from the method of synthesis of the compd. and from the structure of its condensation products, it is evident that J. and G. mean Et α -benzoyl- β -phenylpropionate.—ABSTR.) $\text{BzCH}(\text{CH}_2\text{Ph})\text{CO}_2\text{Et}$ (A), b_p 218–20°, prep'd. by the interaction of PhCH_2Cl and $\text{BzCHNaCO}_2\text{Et}$ in EtOH, when condensed with phenols in the presence of suitable condensing agents gave rise to benzo- γ -pyrones. $m\text{-C}_6\text{H}_4(\text{OH})_2$ in glacial AcOH reacting with (A) in the presence of dry HCl formed 7-hydroxy-2-phenyl-3-benzylbenzo- γ -pyrone (7-hydroxy-3-benzylflavone) (B),

solving in H_2SO_4 with a yellow color and developing an intense, bluish violet fluorescence. Its acetate, colorless needles, m. 134° , develops a similar fluorescence in H_2SO_4 . When heated with KOH for several hrs., (B) is decomp'd. into $\text{BzCH}_2\text{CH}_2\text{Ph}$, m. 72° , and 2,4-(HO) $_2$ $\text{C}_6\text{H}_3\text{CO}_2\text{H}$, m. 203° . The condensation of pyrogallol and (A) yielded 7,8-dihydroxy-2-phenyl-3-benzylbenzo- γ -pyrone (7,8-dihydroxy-3-benzylflavone), leaflets, m. $136\text{--}7^\circ$, developing a green fluorescence in H_2SO_4 , and forming a reddish brown sodium salt; an acetate (0.5 H_2O), needles, m. 175° ; and a benzoate, needles, m. $170\text{--}1^\circ$. Similarly α -naphthol and (A) in the presence of H_2SO_4 or SnCl_4 gave rise to 2-phenyl-3-benzyl-1,4- α -naphthapyrone (3-benzyl-1,4- α -naphthylflavone), leaflets, m. 71.5° , dissolving in H_2SO_4 with a yellow color and greenish fluorescence. $\text{sym-C}_6\text{H}_3(\text{OH})_3$ in AcOH and (A) react in the presence of ZnCl_2 to form 5,7-dihydroxy-2-phenyl-3-benzylbenzo- γ -pyrone (5,7-dihydroxy-3-benzylflavone), pale brown prisms, m. 119° (decomp. 126°). Its acetate, prisms, m. 56° . Similarly 3,5-(HO) $_2$ $\text{C}_6\text{H}_3\text{Me}$ and (A) gave rise to 7-hydroxy-2-phenyl-3-benzyl-5-methylbenzo- γ -pyrone (7-hydroxy-3-benzyl-5-methylflavone), lemon-yellow needles, m. 108° , developing a green fluorescence in H_2SO_4 . $m\text{-C}_6\text{H}_4(\text{OH})_2$ or 1,2,3-(HO) $_3$ C_6H_3 reacting with $\text{PhCH}_2\text{COCHPhCO}_2\text{Et}$ in the presence of concd. H_2SO_4 yielded 1,3-dihydroxy-2-phenylnaphthalene (cf. Volhard, *Ann.* 296, 16(1897)). Very similarly, substituted benzo- γ -pyrones were obtained by condensing $\text{AcCHPhCO}_2\text{Et}$ (C) or $\text{HCOCHPhCO}_2\text{Et}$ (D) with phenols in the presence of suitable condensing agents. (C) reacting with $m\text{-C}_6\text{H}_4(\text{OH})_2$ yielded (in the presence of concd. H_2SO_4) 7-hydroxy-3-phenyl-2-methylbenzo- γ -pyrone (E), needles, m. 226° ; acetate, needles, m. 185° ; benzoate, needles, m. $187\text{--}8^\circ$; ethyl ether, prisms, m. $89\text{--}90^\circ$; methyl ether, needles, m. 87° . On decompn. with 33% alkali (E) yielded 2,4-(HO) $_2$ $\text{C}_6\text{H}_3\text{CO}_2\text{H}$ and AcCH_2Ph . By a similar condensation, 1,2,3-(HO) $_3$ C_6H_3 and (C) yielded 7,8-dihydroxy-3-phenyl-2-methylbenzo- γ -pyrone, pale yellow prisms, m. 268° ; acetate, needles, m. 211° ; benzoate, yellow prisms, m. 204° ; ethyl ether, needles, m. 132° . (C) and α -naphthol reacted to form 3-phenyl-2-methyl-1,4- α -naphthapyrone, $\text{C}_{18}\text{H}_{16}\text{O.CMe:CPh.CO}$, lemon-yellow needles, m. 209° , yielding AcCH_2Ph and 1,2-

$\text{C}_6\text{H}_3(\text{OH})\text{CO}_2\text{H}$ on hydrolysis with KOH. (C) and $\text{sym-C}_6\text{H}_3(\text{OH})_3$ in the presence of ZnCl_2 formed 5,7-dihydroxy-3-phenyl-2-methylbenzo- γ -pyrone, lemon-colored needles, m. 178° ; acetate, needles, m. 146° . (D) and $m\text{-C}_6\text{H}_4(\text{OH})_2$ in the presence of ZnCl_2 gave rise to 7-hydroxy-3-phenylbenzo- γ -pyrone, pale yellow needles, m. 131° . Resorcinol when condensed with $\text{AcOCH}(\text{CO}_2\text{Et})_2$ (F) in the presence of H_2SO_4 formed β -methylumbelliferone. Similarly $\text{AcCHBzCO}_2\text{Et}$ (G) and resorcinol gave rise to β -phenylumbelliferone. Apparently the direction of the condensation with phenols depends on the reactivity of the α -H atom in the acetoacetate. When the H atom is very reactive (as in the case of (F) and (G) where it is situated between 3 C:O groups) coumarins are formed. If its reactivity is sufficiently limited, benzo- γ -pyrones are the result. No definite reaction product could be isolated from a mixt. of m -cresol and $\text{AcCHPhCO}_2\text{Et}$ kept in the presence of H_2SO_4 .

LOUIS E. WISE.

Nitrocamphor and its derivatives. VIII. Action of formamide on nitrocamphor. THOMAS M. LOWRY AND VICTOR STREELE. Guy's Hosp., London. *J. Chem. Soc.* 107, 1038-43(1915).—The following is an improved method for the prepn. of pure nitrocamphor (*A*) m. 102° (cf. *Ibid* 73, 995(1898)). 276 g. of crude bromonitrocamphor were dissolved in 100 cc. of hot EtOH (distd. from KOH) and gradually added to a soln. of 46 g. Na in 400 cc. alc. in a flask provided with a reflux condenser. At the close of the reaction a Na salt sepd. which after washing with EtOH-acetone mixt. (1:1) and acidification yielded pure (*A*). The action of KMnO_4 on isonitrosocamphor also gives rise to (*A*) in theoretical amt. The stable ammonium salt of (*A*), m. 178° , $[\alpha]_{\text{D}}^{25}$ 384° ; $[\alpha]_{\text{D}}^{1780}$ 324° , was formed either by adding HCONH_2 to (*A*) in AcOEt or more conveniently by adding concd. NH_4OH to (*A*) in acetone. When a mixt. of 20 g. (*A*) and 5 g. HCONH_2 in 50 cc. of AcOEt is heated for 12 hours under reflux, and 0.5 of the AcOEt is allowed to evaporate, the residue yields only a small amt. of the NH_4 salt and a new anhydride of (*A*), $\text{C}_{20}\text{H}_{32}\text{O}_5\text{N}_2$ (*B*), slender needles with a slight greenish yellow tint, m. 184° , $[\alpha]_{\text{D}}^{25}$ in C_6H_6 -6° , $[\alpha]_{\text{D}}^{1780}$ -4° . (*B*) is apparently closely related to but not identical with an isomeric anhydride of (*A*); (*C*) previously prepd., m. 193° , $[\alpha]_{\text{D}}^{25}$ in C_6H_6 242° , $[\alpha]_{\text{D}}^{1780}$ 204° . In view of the fact that the reactions of (*B*) and (*C*) are sensibly the same, L. and S. suggest that the compds. are stereoisomers and owing to the low $[\alpha]$ of (*B*) and the high $[\alpha]$ of (*C*) represent their structures by the following formulas:

LOUIS E. WISE.

Reactivity of the halogens in organic compounds. VIII. Interaction of alkalis and alkali bromoacetates in methyl-alcoholic solution. GEORGE SENTER AND HENRY WOOD. Birkbeck Coll., London. *J. Chem. Soc.* 107, 1070-80(1915).—Owing to the comparatively meager data given by Madsen (*C. A.* 7, 3120), S. and W. have repeated M.'s expts. and extended his work, and have shown that M.'s conclusions are not accurate. The reaction between $\text{CH}_2\text{BrCO}_2\text{Na}$ (*A*) and MeONa in MeOH is pseudo-bimol. in character. The course of any one reaction may be satisfactorily represented by the equation for a bimol. reaction, although the speed of reaction is not proportional to the mol. concn. of each of the reacting substances when the initial concns. are varied. MeOK when substituted for MeONa in the above reaction was shown to be considerably more reactive. In the corresponding reaction between $\text{CH}_2\text{BrCH}_2\text{CO}_2\text{Na}$ (*B*) and MeONa , which is much slower than in the case of (*A*), the reaction velocity is not independent of the MeONa concn. (as M. states) but increases with growing concn. of MeONa although not in the same proportion. The actions of MeONa and of MeOH on (*B*) proceed at comparable rates (whereas the action of MeOH on (*A*) is negligible when compared with that of MeONa). Measurements of the halogen displacement in (*A*) and (*B*) in mixts. of MeOH and H_2O have been made with the result that a max. velocity is observed in mixts. containing about 60% H_2O , the velocity coeff. in this case being nearly double that in H_2O and more than twice that in pure MeOH . The relative proportions of Me-acid to HO-acid formed were shown always to be much greater than corresponds with the concn. of MeOH in the mixt. These facts are analogous to those reported by Lobry de Bruyn and Steger (*Rec. trav. chim.* 18, 41, etc.(1899)) on the displacement of a NO_2 group in $p\text{-C}_6\text{H}_4(\text{NO}_2)_2$, and of I in alkyl iodides, in $\text{MeOH-H}_2\text{O}$ mixts. de B. and S.'s results are critically discussed. The methods for detg.

velocities have been previously described. The results of measurements are given in tabular form.

LOUIS E. WISE.

Preparation of dichlorodinitromethane by the simultaneous nitration and chlorination of acetone. JIRENDRA N. RAKSHIT. Presidency Coll., Calcutta. *J. Chem. Soc.* 107, 1115-7(1915).— $\text{Cl}_2\text{C}(\text{NO}_2)_2$ (A), pale yellow liquid, b. $121-2.5^\circ$, possessing an extremely pungent odor (cf. Losanitsch, *Ber.* 17, 849(1884), and Marignac, *Ann.* 38, 16(1841)), was readily prepd. by the following method: To a mixt. of 60 g. granular CaCl_2 and 40 cc. of acetone in a H_2O -cooled flask were very gradually added through a tap funnel 10 cc. of 70% HNO_3 . After 5 min., 5 cc. more of HNO_3 were slowly added and the addition of acid continued until the beginning of a violent reaction (after about 20 min.), during which NO_2 , Cl and NOCl were evolved. When fuming had ceased, more HNO_3 was gradually added until all of the CaCl_2 had dissolved. The upper layer in the flask was then sepd. and transferred to another well-cooled flask containing 40 g. of CaCl_2 and treated as before with HNO_3 . At the conclusion of this second reaction, the upper layer in the flask was subjected to a third similar treatment. The entire expt. was completed during 1 day, the time of reaction being about 6 hrs. The final upper layer when poured into H_2O yielded about 12 cc. of an insol. heavy oil, which consisted largely of (A), and which after drying was purified by fractional distn. The synthesis should be carried out exactly as described, with the quantities indicated, since a violent explosion followed the use of larger proportional amts. If the reaction mixt. was allowed to stand overnight in contact with HNO_3 , a colorless liquid (not (A)) containing 8.38% C, 9.97% N, and 48.86% Cl was formed.

LOUIS E. WISE.

Hydrazides and azides of organic acids. XXXI. The hydrazides and azides of oxalic acid. THEODOR CURTIUS with KARL HOCHSCHWENDER. *J. prakt. Chem.* 91, 415-41(1915); cf. *C. A.* 9, 1605.—The following members of this series have been previously prepd.: $(\text{CONHNH}_2)_2$ (a) (Schöfer and Schwan, *J. prakt. Chem.* 51, 194), oxazide (b), $(\text{N}_3\text{CO})_2$ (Burkhardt, *J. prakt. Chem.* 58, 216, 232), $\text{HO}_2\text{CCONHNH}_2$ (c) (Curtius, Darapsky and Müller, *C. A.* 1, 1573) and $\text{NH}_2\text{OCCONHNH}_2$ (d) (Kerp and Unger, *Ber.* 30, 586). $\text{HO}_2\text{CCO}_2\text{N}_3\text{H}_5$ (e) is formed when $(\text{CO}_2\text{H})_2$ and 1 mol. $\text{N}_3\text{H}_4\cdot\text{H}_2\text{O}$ are dissolved in H_2O and cooled; short, stout needles from H_2O , shrivels 180° without m.; 1 part H_2O dissolves 0.006 part of salt. $(\text{CO}_2\text{N}_3\text{H}_5)_2$ (f), formed when 2 mols. $\text{N}_3\text{H}_4\cdot\text{H}_2\text{O}$ are used, seps. on evapn. *in vacuo* in fine needles, which soften 140° and m. 148° . (e) and (f) have both been described since the completion of this work, by Turrentine, *C. A.* 4, 2266. 10 g. (d), heated at 100° for 2 hrs. with 50 g. Ac_2O gives in 66% yield the *diacetyl derivative*, $\text{H}_2\text{NOCCONHNHAc}$, lustrous needles from alc. or H_2O , m. $184-5^\circ$; *benzoyl derivative*, by shaking 5 g. (d) in H_2O with 10 g. Na_2CO_3 and 15 g. BzCl , fine needles in clusters from H_2O , m. $231-2^\circ$; yield 75%. *Oxamyl azide* (g), $\text{H}_2\text{NOCCON}_3$, is obtained in 22.8% yield when 30 g. HCl (d) in 50 cc. H_2O is treated at -5° with 15 g. NaNO_2 in H_2O drop by drop with shaking; the slimy mass is quickly filtered, sepd. from *hydrazidioxamide* (h), $(\text{H}_2\text{NOCCONH})_2$, by soln. in 1.6 kg. acetone, filtered and pptd. by 2 vols. cold petr. ether; microscopic needles and leaves, which explode violently 115° ; boiled with alc., $\text{NH}_2\text{CONHCO}_2\text{Et}$ is formed (the corresponding diazide (b) is not attacked by alc.); warmed with H_2O , the formation of $\text{CO}(\text{NHCONH}_2)_2$ was to be expected, but $\text{NH}_2\text{COCO}_2\text{H}$ was the only product isolated; warmed at $30-40^\circ$ with moist AcMe , $\text{CO}(\text{NH}_2)_2$ is formed, probably as follows:

$$\text{NH}_2\text{COCON}_3 \xrightarrow{+\text{H}_2\text{O}} \text{NH}_2\text{CONHCO}_2\text{H} \xrightarrow{-\text{CO}_2} \text{CO}(\text{NH}_2)_2$$

With PhNH_2 and $p\text{-NH}_2\text{C}_6\text{H}_4\text{Me}$ in acetone, (g) gives $\text{NH}_2\text{CONHCONHPh}$ (Schiff, *C. A.* 1, 1700) and asym. *p*-tolylbiuret (Pickard and Carter, *J. Chem. Soc.* 79, 844), resp., while PhNHNH_2 in Et_2O gives $\text{NH}_2\text{COCONHNHPh}$, without rearrangement. (h) is formed exclusively

in 55% yield when HCl (*d*) is treated at room temp. with 0.5 mol. NaNO_2 ; sparkling flakes from H_2O , sol. in Na_2CO_3 and alkalis, m. $302-3^\circ$ (decompn.); *silver salt*, yellow. HNO_2

The reaction probably proceeds as follows: $\text{NH}_2\text{NHCOCOCONH}_2 \xrightarrow{\text{HNO}_2} \text{N}_2\text{COCONH}_2$
 $\text{NH}_2\text{NHCOCOCONH}_2$

$\longrightarrow [\text{NH}_2\text{COCONH}]_2 + \text{HN}_2$ (cf. Curtius, *J. prakt. Chem.* 52, 468). (*k*) is also formed, but in smaller yield, by heating (*d*) in alc. with I at 100° . While the neutral esters of dibasic acids in general react with $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$ to form dihydrazides, even though the ester is present in excess, $(\text{CO}_2\text{Et})_2$ gives chiefly the monohydrazide, *ethyl hydrazino-oxalate* (*i*), $\text{NH}_2\text{NHCOCO}_2\text{Et}$. To 90 g. $(\text{CO}_2\text{Et})_2$ in 50 cc. alc., 20 g. $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$ is added slowly, keeping the temp. below -13° , the soln. then filtered from about 2 g. of the dihydrazide, evapd. *in vacuo* at 30° and Et_2O added in large excess, when (*i*) seps. as an oil which crysts. on cooling in short, stout needles, m. $52-3^\circ$, effervescing and then solidifying at 152° and not again m. below 300° ; it is unstable, decomp. to a high melting substance on standing; with NH_3 , it gives (*d*) and with BzH the benzal derivative of Stollé, *C. A.* 5, 1914; acetone does not give a cryst. condensation product; the *hydrochloride* (*j*), formed in 89-94% yield from a cold Et_2O soln. with dry HCl, hygroscopic leaves or powder, m. $107-8^\circ$. *Ethyl asido-oxalate* (*k*), $\text{N}_2\text{COCO}_2\text{Et}$, is formed when 10 g. (*j*) in a little H_2O is covered with 100 cc. Et_2O , treated cold with 4.1 g. NaNO_2 in 20 cc. H_2O , the Et_2O layer sepd. and evapd.; an oil, which explodes violently on heating. The H_2O layer from the above expt., satd. with $(\text{NH}_4)_2\text{SO}_4$, extd. with CHCl_3 , the CHCl_3 soln. dried and dild. with ligroin, seps. *diethyl hydrazidioxalate* (*l*), $(\text{EtO}_2\text{CCONH})_2$, in fine needles, m. $125-6^\circ$. To prep. (*l*) alone by the action of NaNO_2 on (*j*), the reaction is carried on in H_2O at room temp., using only 0.5 mol. NaNO_2 ; yield, 6 g. from 20 g. (*j*). It cannot be prepd. like (*k*) by the action of I on (*i*), but is formed when (*i*) in alc. is oxidized with 2 mols. HgO or (*i*) is heated with 4 mols. $(\text{CO}_2\text{Et})_2$ at $130-40^\circ$; the yields in both cases are poor. (*l*) is converted by NH_3 into (*h*). When (*k*) is warmed with alc., $\text{NH}(\text{CO}_2\text{Et})_2$ is formed. When 4 g. (*l*) are treated with 3 mols. NaOH in 20 cc. H_2O , a cryst. *sodium salt* seps., which is probably $\text{NaO}_2\text{CCONHNNaCOCO}_2\text{Na}$; on acidifying the H_2O soln., *hydrazidioxalic acid* (*m*), $(\text{HO}_2\text{CCONH})_2$, is pptd., which m. $174-5^\circ$. If (*m*) is crystd. from hot H_2O , the *hydrate*, (*m*) $\cdot 3\text{H}_2\text{O}$, seps. in short needles or leaves, which m. 126° , solidify 170° and do not again m. below 280° . From H_2O solns. of (*m*), AgNO_3 and $\text{Pb}(\text{OAc})_2$ give white ppts., CuSO_4 a green ppt. sol. in NH_3 , and $\text{CaCl}_2 + \text{NH}_3$ a white gelatinous ppt. When $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$ in abs. alc. is added to (*l*) in abs. alc., *hydrazidioxalyl dihydrazide* (*n*), $(\text{NH}_2\text{NHCOCOCONH})_2$, is pptd. as a white gelatinous mass, which becomes granular on heating; fine, long needles from H_2O , which do not m. below 300° ; *dihydrochloride*, pptd. from dil. HCl by concd. HCl; *nitrate*; *dibenzal derivative*, microscopic cryst. powder, m. above 300° . *Hydrazidioxalyl diaside*, $(\text{N}_2\text{COCONH})_2$, is formed in the usual manner by the action of HNO_2 on (*n*); cryst. powder, which explodes violently on heating; heated with abs. alc. at 100° , N_2 is evolved, leaving a white cryst. powder on evapn., small, rhombic tables from alc., m. $200-5^\circ$, which were identified as the *déurethos derivative*, $[\text{EtO}_2\text{CNHCONH}]_2$, by the products of hydrolysis, alc., CO_2 , NH_3 , N_2H_4 and no $(\text{CO}_2\text{H})_2$.

The biochemistry of respiration. H. M. VERNON. *Sci. Prog. Twentieth Century* 9, 251-69(1914); *Expt. Sta. Record* 32, 664.—A summary and digest of data regarding this subject, from which V. draws the general conclusion that the biochemistry of respiration is in the main dependent upon intracellular enzymes. While in some instances this is entirely a hydrolytic process without oxidation, in a majority of organisms the processes are both hydrolytic and oxidative. E. J. C.

Cause of the activation exerted by beer yeast on the gastric juice. II. GIOVANNI PICCOLI. Univ. Bologna. *Arch. farm. sper.* 19, 488-504(1915).—The favorable action of yeast on peptic digestion is probably due to the presence of erepsin. Since this enzyme increases in amt. as the cells multiply, and is therefore a product of the activity and not of the destruction of yeast cells, the amt. of protein digested should be greatest under conditions that promote the growth of yeast. A. W. DOX.

Influence of the bromine-ion on uricolysis. ANTONIO JAPPELLI. Univ. Naples. *Arch. farm. sper.* 19, 329-34(1915).—NaBr inhibits the enzymic oxidation of uric acid by liver exts. *in vitro*, as compared with similar concns. of NaCl. This furnishes further verification of J.'s previous findings that the Br-ion has an inhibitory effect upon enzymes in general. A. W. DOX.

Researches on the permeability to glucose of the red corpuscles of splenectomized dogs. A. DONATI. Univ. Torino. *Arch. farm. sper.* 19, 565-71(1915).—Splenectomy increases the permeability of the erythrocytes to glucose. This effect cannot be due to the formation of new cells, since these are known to be less permeable to glucose than the mature cells. A. W. DOX.

Certain aspects of biological oxidation. A. S. LOEVENHART. Univ. Wisc. *Arch. Intern. Med.* 15, 1058-71(1915); cf. *C. A.* 7, 2062; 8, 175, 752, 1468, 1994.—The effect of the administration of CO or of NaCN is explained as due to their effect in diminishing oxidations. The primary effect is stimulation of the medullary centers. The administration of Na iodo- and iodosobenzoate, which contain active O and which accelerate oxidations, depresses these centers. These substances also produce effects on the formation of hemolysins and reaction to foreign substances which are in marked contrast to the inactivity of Na iodobenzoate. Expts. on rabbits kept at normal atmospheric pressures but with varying concns. of O and of CO₂ showed that when the concn. of O is reduced to 0.5 of the usual amt. there is an increase in the number of erythrocytes, or amt. of hemoglobin in the blood, or both. Blood-smears showed that the effect was not due to concn. of the blood but to stimulation of the bone-marrow. Increased concn. of CO₂ stimulated the respiratory center but had little effect on the bone-marrow. When the concn. of O in the atm. is reduced to 3 or 3.5%, rabbits soon die, but at concns. slightly above this they behave normally. Various chem. combustions are completely inhibited long before the O concn. has sunk to any such level: EtOH at 15%, illuminating gas at 13%, H₂ at 6.6%. I. GREENWALD.

The role of oxidases in respiration. G. B. REED. Harvard Univ. *J. Biol. Chem.* 22, 99-111(1915); cf. *C. A.* 7, 3602.—The formation of indophenol from *p*-phenylenediamine and α -naphthol frequently proceeds most rapidly in the region of semipermeable membranes, yet many surfaces show no such activity. The semi-

permeable character of the membrane may be destroyed by suitable means (CHCl_3 , toluene, etc.) without interfering with the formation of indophenol within the cells. Such treatment does not affect the activity of oxidases. If, however, the cell be killed by such means as are known to destroy oxidases, no formation of indophenol occurs. It is concluded that the oxidases are the essential agents in the formation of indophenol.

I. GREENWALD.

Studies of autolysis. II. The acceleration of liver autolysis. H. C. BRADLEY. Univ. Wisc. *J. Biol. Chem.* 22, 113-23(1915); cf. *C. A.* 9, 1920.—Casein, peptone and coagulated liver proteins are digested by the autolytic enzymes of the liver. The presence of MnCl_2 does not lead to an increase in the rate or the extent of digestion of casein or of peptone. Edestin is not digested by the liver enzyme under normal conditions, but is digested when MnCl_2 is added. Ovalbumin is not digested by the liver enzymes, even if MnCl_2 be added. In the presence of HCl , it is digested. All the sol. salts of Mn investigated accelerate and increase liver autolysis. The phosphate (insol.) does not and the carbonate, which inhibits the formation of the normal acidity of the liver pulp, does inhibit autolysis. A lower concn. of HCl acts as does MnCl_2 in accelerating and increasing autolysis. Although in H_2O soln. the MnCl_2 used would not have as high a H^+ concn. as the HCl that produces the same effect upon autolysis, in the liver pulp, fixation of ions by protein permits further hydrolysis of MnCl_2 . It is therefore probable that the effect of the MnCl_2 (and of other Mn salts) is entirely due to the acid liberated from them.

I. GREENWALD.

The role of halogens as accelerators of tissue enzyme action. MAX MORSE. Univ. Wisc. *J. Biol. Chem.* 22, 125-32(1915).—I and iodides may slightly accelerate the rate of autolysis of liver tissue. This may be due to the formation of small amts. of HI . Thyroid protein and iodized blood-protein cause an apparent acceleration of autolysis, probably due to the increase in available substrate. The addition of small amts. of Br accelerates autolysis, probably because of the increased acidity. Feeding of the dog with thyroid for 2 weeks previous does not increase the rate of autolysis of the liver.

I. GREENWALD.

The formation of yeast protein from inorganic nitrogen compounds. ED. DONATH. *Oesterr. Chem. Ztg.* 18, 74(1915).—D. demonstrates that from a purely scientific standpoint the credit for this discovery belongs to Ad. Meyer.

ARTHUR LEDERER.

Some new constituents of milk. I. The phosphatides of milk. THOMAS B. OSBORNE AND ALFRED J. WAKEMAN. Conn. Agr. Expt. Sta. *J. Biol. Chem.* 21, 539-50(1915).—The phosphatides were obtained by repeated hot alc. extn. of the coagulum resulting from boiling milk serum after the pptn. of the caseinogen from 3000 l. of milk with 1% HCl . The ext. was concd. at a low temp. *in vacuo*, the residue dissolved in Et_2O , shaken out with H_2O and the Et_2O distd. off. The residue was extd. repeatedly with Me_2CO ; an amt. failed to dissolve equal to 0.31% of the coagulum. The material insol. in Me_2CO had all the physical properties of lecithin. It was only partly sol. in Et_2O . The portion insol. in Et_2O , after repeated crystn. from warm alc., sepd. in the form of semi-cryst. microscopic balls; turns brown and softens above 169° , begins to melt at 184° , m. 190° (decompn.) to a clear brown liquid; absorbs 29.8% of I; ratio of P:N equal to 1:2.09. The substance was apparently a diamino-phosphatide but lack of material made it impossible to det. its nature. The phosphatide, sol. in Et_2O , was purified by twice dissolving in Et_2O and pptg. with excess of Me_2CO . It was a monoaminophosphatide, yielding choline containing at least $\frac{1}{2}$ of the N, fatty acids and glycerophosphoric acid in proportions corresponding to a stearyl-oleyl-lecithin of the structure commonly assumed for this substance. About 36% of the N of the phosphatide is present in the form of amino-N and it is probable that the Et_2O -sol. milk phosphatide is a mixt. of 2 substances, one yielding choline and the other

a base containing amino-N. "What relation these substances have to the protein is difficult to det. That some form of combination exists must be assumed, for they become sol. in Et_2O only after the protein is treated with alc., and, furthermore, before coagulating by heat, they are freely sol. in H_2O . It is probable that these phosphatides are not combined with the lactalbumin which is the chief constituent of the coagulum, but with another protein, for we found that when the filtrate from the casein is neutralized with milk of lime the acidified filtrate from the ppt. yields a coagulum which is free from P. Since the ppt. produced by thus neutralizing contains protein, it is probable that the phosphatides are also contained therein as a lecithalbumin containing a relatively large proportion of phosphatide similar to ovovitellin of the egg-yolk."

A. P. LOTHROP.

Action of serum on the lipase of pancreatic juice. J. A. SHAW-MACKENZIE. *J. Physiol.* 49, 216-21(1915).—The author confirms his previous expts. and contradicts the statements of Mellanby and Woolley. (1) Pancreatic lipase can be sepd. into enzyme and coenzyme. (2) Blood serum contains a coenzyme to which is due its accelerating effect on lipase. (3) Lipase can exist in the presence of free trypsin although its activity is somewhat reduced. (4) Glycerol exts. of pancreas contain active trypsin. (5) Fresh pancreatic juice contains little active lipase, the enzyme being present as pro-lipase.

J. F. LYMAN.

Enzymes of the pancreas. V. Carbohydrate enzymes of pancreatic juice. J. MELLANBY AND V. J. WOOLLEY. *J. Physiol.* 49, 246-64(1915).—Fresh pancreatic juice contains amylase but no maltase. The amylase breaks down starch into a stable dextrin (25%) and maltose (75%). After adding acid to pancreatic juice maltase and an enzyme capable of hydrolyzing the stable dextrin are produced. The greater the H^+ concn. the greater the amt. of dextrose formed until a concn. of acid is present which stops all action owing to the destruction of the enzyme. Maltose is 54% hydrolyzed under optimal conditions of acidity. Hydrolysis of starch is facilitated by neutral salts as CaCl_2 , or NaCl , but the final position of equil. is the same as when pancreatic juice only is present. It is suggested that pancreatic juice contains 1 carbohydrate enzyme. In a neutral medium, or in the presence of neut. salts, this enzyme hydrolyzed starch to dextrin and maltose only. When acid is added the enzyme associates itself with some of the acid and the activity of the enzyme is detd. by the H^+ concn. of the enzyme complex. Pancreatic juice alone, or in the presence of neutral salts, acids or alkalies, has no action on lactose or sucrose.

J. F. LYMAN.

The rate of evaporation of ether from oils and its application in oil-ether colonic anaesthesia. CHAS. BASKERVILLE. College of City of N. Y. *J. Ind. Eng. Chem.* 7, 868-70(1915); *Proc. Am. Phil. Soc.* 54, 270-8(1915).—Report of an experimental study covering: (1) A comparison of the rate of evapn. of ether from different mixts. of ether and the same oil, (2) a comparison of the rate of evapn. of ether from the same per cent. mixts. of different oils and ether, and (3) the influence of surface on the rate of evapn. The oils were of 3 types, vegetable, animal and mineral. The method of procedure involved heating in a thermostat to 37° . The observations demonstrated that: (1) While ether boils at 34.6° , it does not escape violently from an oil-ether mixt., as from an aqueous mixt., when the mixt. is heated higher, namely to the body temp. (37°). (2) The rate of sepn. of ether from the oil quickly acquires a definite and fairly fixed speed. This conduct, it is thought, may be utilized to maintain in the blood any desired physiological effect of ether that has a quantitative relation thereto, for example, the third or surgical stage of anaesthesia. The latter effect has been demonstrated clinically, with records to date of about 1000 human cases. **Discussion.** J. T. GWATHMEY. *J. Ind. Eng. Chem.* 7, 870.

STANLEY R. BENEDICT.

Gerhardt's reaction for acetoacetic acid. L. LICHTWITZ. Göttingen. *Berl. klin. Wochschr.* 52, 399-400(1915).—The strength of the FeCl_3 test for acetoacetic acid in urine has no relation to the strength of the sodium nitroprusside test for the same substance. The reason for this is found to be that the ketone and the enol forms of acetoacetic acid do not occur in the same proportion in urine and Gerhardt's test detects only the enol form while the sodium nitroprusside test is for the ketone form.

JULIAN H. LEWIS.

Chemical analysis of shot-marks. T. LOCHTE AND E. DANZIGER. *Vierteljahreschr. ger. Med.* 49, 7-14(1915).—Flobert shots made with a Flobert pistol at short range (10 cm.), showed 8 mg. of Pb in the wound. At a range of 4 m. the Pb content was 0.07-8 mg. With revolver shots and similar range, 0.4 mg. Pb at most were shown. Gunshots with Pb bullets at a distance of 1 m. show traces of Pb (0.04-7 mg.). Traces disappear at a distance of 2 m. L. and D. state that a conclusion as to the distance cannot be drawn with mathematical safety from traces of Pb, but only with a certain probability.

EDWARD J. KELLEY.

The value of the clinical, pathological-anatomical, chemical and legal examinations into phosphorus poisoning. J. P. L. HULST. *Vierteljahreschr. ger. Med.* 49, 206-20(1915).—A discussion. The author finds considerable value in the above examinations.

EDWARD J. KELLEY.

An accurate clinical study of blood-sugar. SOLOMON STROUSE, IRVING F. STEIN AND ALAN WISELY. Chicago. *Bull. Johns Hopkins Hosp.* 26, 211-5(1915).—Calibrate several ordinary centrifuge tubes, marking them at the 0.5, 1, 5 and 10 cc. points. Fill a tube to the 0.5 cc. mark with 0.2% NaF soln. Allow blood from a pricked finger or ear to fall into the tube up to the 1 cc. mark. Add H_2O to the 5 cc. mark and a pinch of powdered Rochelle salt and shake until soln. is complete. Add Merck's dialyzed Fe (5%) soln. up to the 10 cc. mark, stopper and shake vigorously until the mixt. is homogeneous. Centrifuge 3-5 min. Proceed with the detn. according to the method of Kowarsky (*C. A.* 7, 3768). A table is given from which the amt. of sugar can be read directly from the Cu content of the ppt. The amt. of sugar in the Cu soln. must be subtracted from the amt. found. If the supernatant liquid after centrifuging is not water-clear more of the dialyzed Fe soln. should be used. The detn. can be made in 15 min. and is especially useful for clinical purposes. In a series of 61 detns., the normal blood-sugar varied from 0.04 to 0.12% with an av. of 0.084%. "Carbohydrates in the diet raise the blood-sugar. The blood-sugar of a normal man describes a curve reaching its lowest limits before breakfast and before dinner, and invariably showing a rise 1 hr. after meals. Detns. to be of any value must be performed before and after an ordinary meal containing carbohydrate."

Renal functional tests. JOHN T. GERAGHTY. Baltimore. *Bull. Johns Hopkins Hosp.* 26, 155-8(1915).—A discussion of the value of the various renal functional tests.

A. P. LOTHROP.

A rapid method for determining calcium in urine and feces. HENRY LYMAN. Harvard Med. School. *J. Biol. Chem.* 21, 551-6(1915).—A method has been devised in which the Ca is pptd. as a soap and the cloud formed is compared with a cloud of a standard soln. in the Duboscq colorimeter. From 5 to 10 cc. of urine (8 cc. will usually give the best results with normal adults on a mixed diet) are measured into a small Erlenmeyer flask and the Ca pptd. as oxalate according to the method of McCrudden. On account of the small vol. of urine used for the detn., 1 cc. of 2% $(\text{CO}_2\text{H})_2$ and 1 cc. of 10% Na acetate are used in the pptn. After shaking for 10 min., pour into a centrifuge tube, rinsing the flask with 2 cc. of 0.5% $(\text{NH}_4)_2\text{C}_2\text{O}_4$ soln. Centrifuge until

the supernatant liquid is perfectly clear (2-3 min.). Decant, being careful not to disturb the ppt., wash with 10 cc. of 0.5% $(\text{NH}_4)_2\text{C}_2\text{O}_4$, centrifuge and decant. Dissolve the ppt. in 5 cc. of 5% HCl, warming in hot H_2O , if necessary. Pour the soln. into the flask in which the original pptn. was made and wash out the tube with 5 cc. of H_2O . Dissolve any ppt. clinging to the walls of the flask by agitating the liquid. In another flask measure 10 cc. of a standard soln. of CaC_2O_4 in 2.5% HCl, containing 1.5 mg. of Ca per 10 cc. (0.5475 of $\text{Ca}_2\text{C}_2\text{O}_4 \cdot \text{H}_2\text{O}$ in 1 l. of 2.5% HCl). From a pipet, from which the tip has been broken, run into each flask 20 cc. of K ricinate soln., shaking during the addition. Mix, allow to stand for 2 min. and read the clouds in the Duboscq colorimeter. If the amt. of urine taken is found to contain less than 0.75 mg. or more than 2.5 mg. of Ca, the readings are not quant. and another detn. must be made with a vol. of urine which will give results between these amts. Diln. after pptn. will not give accurate results. If 10 cc. of urine are used and the *unknown* is set at 15 mm., the reading of the standard equals the mg. of Ca in 100 cc. of urine. Formula: (reading of the standard $\times 1.5$) / (height at which the unknown is set $\times$ number of cc. of urine taken) = mg. of Ca in 1 cc. The shade of the colorimeter must always be used; daylight from a clear sky is the best (artificial light containing much yellow or red cannot be used); the colorimeter must be kept perfectly clean and should always be tested with the standard in both cups. The K ricinate is prepared as follows: dissolve 15 g. of KOH in 25 cc. of H_2O and 100 cc. of alc., warm and add 100 cc. of castor oil. Shake well and heat under a reflux condenser until sapon. is complete (about 7 hrs.). Of this stock soln., pipet 35 cc. into a flask and add 965 cc. of distd. H_2O in which have been dissolved 9 g. of NaOH (KOH does not give good results). The reagent should be perfectly clear and must be made fresh from the stock soln. once a week. In the analysis of feces, weigh out 5-6 g., after thorough mixing, into a silica dish, moisten with concd. H_2SO_4 and burn to a white powder, heating gently at first. Wash the residue into a 100 cc. volumetric flask with 50 cc. of 10% HCl, make up to vol., shake and filter. Take 50 cc. of the filtrate and make up to 100 cc. with distd. H_2O . Det. the Ca in this soln. by the method described except that 2 cc. of Na acetate soln. must be added instead of 1 cc.

A. P. LOTHROP.

The quantitative determination of creatine in muscle and other organs. N. W. JANNEY AND N. R. BLATHERWICK. Montefiore Home, N. Y. *J. Biol. Chem.* 21, 567-82 (1915).—The method of Myers and Fine (*C. A.* 8, 1132) has been modified in such a way as to permit the use of very much smaller amts. of material. Free fresh muscle quickly from visible connective tissue, grind in a meat chopper and mix thoroughly. Weigh out into a beaker by difference about 5 g. from a sample in a weighing bottle with ground-glass stopper. Stir up in 50 cc. of H_2O and heat to boiling. Remove the flame and stir through the contents of the beaker 10 cc. of a 15% suspension of powdered $\text{Al}(\text{OH})_3$. Filter hot through a small Buchner funnel into a warmed flask. Ext. the ppt. with 150 cc. of hot H_2O in 6 portions, filling the funnel completely and sucking nearly dry each time. Transfer the filtrate to a flat bottom Jena flask graduated to 300 cc., washing the filter flask with 55 cc. of 25% H_2SO_4 , followed by H_2O until the volumetric flask contains about 280 cc. The acid concn. is approx. *N*. Convert the creatine into creatinine by immersing the flask in a boiling H_2O bath for 3 hrs. Cool, dil. to the mark and mix. Det. the creatinine by the Folin method after neutralizing the acidity to phenolphthalein of 10 cc. of the soln. with 10% NaOH. If the weighing of the material is carefully done, smaller amts. of muscle, $\text{Al}(\text{OH})_3$, vol. of ext. and H_2SO_4 may be safely employed. In analyzing organs other than muscle the same technic is used up to and including the extn. of the creatine, except that at least 5 g. of material should be taken. To the creatine ext. add 8 cc. of 25% H_2SO_4 , transfer to a porcelain dish, washing the filter flask twice with H_2O . Evap.

on a H_2O bath to 75 cc., cover the dish with a large watch glass to retard further evapn. and continue heating for 2 hrs. Transfer the cooled soln. quant. to a 100 cc. flask, dil. to the mark and mix. Det. the creatinine in the usual manner. In working with organs which contain only traces of creatine, measure 10 cc. of the unknown into a small glass, add 20 cc. of satd. picric acid and 1.5 cc. of 10% NaOH in addition to the amt. necessary to neutralize 10 cc. of the unknown. To 10 cc. of the standard add 20 cc. of the picric acid and 1.5 cc. of the NaOH soln. and sufficient distd. H_2O from a buret to make the vol. equal to that of the unknown. In all cases the standard may be set at 20 mm. The method has been compared with that of Folin (*C. A.* 8, 2736) and it was found that "the action of heat and acid on dog muscle leads to the production of products other than creatine, which are the sources of the higher results obtained by the use of the Folin method. Folin's procedure for the estn. of creatine in muscle is of limited applicability. For organs other than muscle it cannot be recommended." Glucose and urea in concns. up to 1% do not interfere provided the colorimetric readings are made promptly. "Creatine and creatinine are probably not to be regarded as existing in firm combination in liver and muscle, as acid hydrolysis of such organs, previously freed of these substances by extn., fails to yield additional creatine or its anhydride." The following amts. of creatine in mg. per 100 g. were found in various organs: dog brain 124, pancreas 18, kidney 27, spleen 30, testes 181, liver 20 (av. of 12 detns.); calf liver 45.

A. P. LOTHEROP.

Determination of total nitrogen in urine, particularly in presence of sugar. ED. JUSTIN-MUELLER. *J. pharm. chim.* 11, 171-4(1915).—Into a 200-250 cc. flask put 10 cc. of urine, 5 cc. of a 30% soln. of $K_2C_2O_4$ and 9 cc. of concd. H_2SO_4 ; then add slowly 20 cc. of H_2O_2 of 12 vols. and heat over a flame. Steady effervescence marks decompn. of the sugar, which, without the use of H_2O_2 , would cause a troublesome black scum to form. Further heating destroys organic matter, and N is detd. as usual. For 10 cc. of urine containing n g. of sugar per l., use $n/2$ cc. of H_2O_2 of 12 vols., and $5 + n/10$ cc. H_2SO_4 .

The action of radium and its emanations on the germination of the higher plants. HENRI AGULHON AND THÉRÈSE ROBERT. *Ann. inst. Pasteur* 29, 261-73(1915).—The expts. here reported concern only the germination of seeds or the period during which the plants live at the expense of their reserves. They are classed in 3 series: (1) Expts. with the Ra in a sealed tube; here the germinating plants are submitted to the emanations which traverse the glass. (2) Expts. with a very dil. soln. of $RaBr_3$, in which the seeds germinate directly. (3) Expts. with the Ra in an unsealed vial, permitting the emanations to diffuse in a closed space in which the cultures are disposed. In the first series, there was clearly a retarding influence exerted by the radia-

tions capable of traversing the glass. In the second series, no action, favorable or unfavorable, was observed. In soln., very small doses of Ra are inactive. The third series of expts. seems to prove a positive activation of the growth of plants by the emanations of Ra. If this activation was due to the presence of ozone, the conc. of the ozone was in each case too slight to be recognized by the most sensitive indicators available.

GEO. T. CALDWELL.

Physiological investigations on the germination of the pollen of *Vitis vinifera*. E. GARINO-CANINA. *Stas. sper. agrar. ital.* 47, 481-92(1914); through *Chem. Zentr.* 1915, I, 322-3.—The pollen of the grape is decidedly acidophile. The best germinative soln. is 15% cane sugar plus 2% neutral gelatin and 1:4000 tartaric acid. A long-continued rain acts on natural germination in the same way as distd. water in expts. Temps. below 14 and above 35° inhibit germination. All the bactericides used in the vineyard are poisons for germination.

Ectoprotease of grapes. F. M. MARRAS. Univ. Sassari. *Centr. Bakt. Parasitenk., II Abt.* 43, 641-4(1915).—Using the gelatin plate method which is the most delicate test for proteolysis, protease could not be detected in the juice expressed from ripe and unripe grapes.

JULIAN H. LEWIS.

The distribution of cyanogen in grasses, especially in the genera, *Panicularia* or *Glyceria* and *Tridens* or *Sieglingia*. C. L. ALSBERG AND O. F. BLACK. U. S. Dept. Agr., Bur. of Plant Ind. *J. Biol. Chem.* 21, 601-9(1915).—Twenty-two species of American grasses were tested for HCN. Of these, this acid was found in *Tridens flavus* and *Panicularia nervata*, *P. grandis* and *P. canadensis*. It was not present under the conditions of examn. in *Panicularia pauciflora*, *P. fluitans* and *P. septentrionalis*. Sleepy grass of the Southwest, *Stipa vaseyi*, which is generally regarded as poisonous, contained no HCN.

A. P. LOTHROP.

The blackening of the leaves of the wild indigo (*Baptisia tinctoria*) and the isolation of a new phenol, baptisol. E. D. CLARK. Cornell Univ. Med. College. *J. Biol. Chem.* 21, 645-60(1915).—Leaves of *Baptisia tinctoria*, subjected to the action of various volatile organic substances, are turned jet black by the vapors. There is a rise in temp. which often reaches 55-60° in an hour in the center of the mass. Substances of the ester type are more effective in causing the blackening of the leaves than the ordinary volatile antiseptics such as CHCl_3 , C_2H_5 , and Et_2O . Me_2CO is the most active agent. "The phenomena of blackening seem to be produced by any agency, physical, chem. or mechanical, that disturbs the normal relationships of the cells containing certain enzymes and those containing the substrate; i. e., altered permeability and active diffusion of the cell constituents. Apparently, first a hydrolytic enzyme decomposes a glucoside, and then an oxidase acts to produce the dark pigment." When the leaves are subjected to the action of CHCl_3 vapors for 24 hrs., they turn jet black and are covered with a white cryst. efflorescence. This substance can be extd. from the leaves by 0.5% NaOH, neutralization by dil. AcOH and extn. of the ppt. with hot 95% alc. After boiling the alc. ext. with bone-black, the compd. is pptd. by diln. of the alc. to 30% with hot H_2O . Fresh leaves which have not been blackened, do not yield the compd. when treated with 0.5% NaOH. The blackened dried leaves contain about 0.2% of the substance. The new phenol has been named baptisol, $\text{C}_{15}\text{H}_{13}\text{O}_5$; m. 212-3° (cor.); insol. in H_2O , sol. in glacial AcOH, concd. HCl, alc., CHCl_3 , etc.; pptd. from soln. in fixed alkalies by dil. acids or CO_2 ; reacts positively with Millon's reagent. *Triacetyl*baptisol, m. 189° (cor.). *Tribenzoyl*baptisol, m. 183° (cor.). The phenol contains 3 hydroxyl groups and 1 methoxy group, but lack of material made it impossible to identify any other groups. "It apparently has no unsatd. bonds, no groups reacting with NH_4OH or PhNHNH_2 , no groups capable of oxidation or re-

duction to form colored products, and none of the properties of flavones as a class." From present knowledge the formula may be indicated as $C_{16}H_{14}O(OCH_3)(OH)_2$.

A. P. LOTHROP.

The presence of choline in the shoots of *Aralia cordata*. K. MIYAKE. Tohoku Imperial Univ., Japan. *J. Biol. Chem.* 21, 661-2(1915); cf. *C. PHILIP B. HAWK.

NORMAL.

Phosphorus metabolism of lambs fed a ration of alfalfa hay, corn, and linseed meal. E. L. ROSS, M. H. KEITH AND H. S. GRINDLEY. Univ. Ill. *J. Agr. Res.* 4, 459-73(1915).—This is part of an investigation to det. the influence of different quantities of protein on nutrition of young lambs. Differences of protein were obtained by varying the proportions of corn and linseed meal. The feces were collected daily at 2 P.M. from oilcloth-lined canvas bags strapped to the lambs. The urine was collected under the animal cages in galvanized iron trays. A large part of the P of alfalfa hay is acid-sol. inorg.; the P of corn is $\frac{1}{2}$ acid-sol., largely org.; that of linseed meal is mostly acid-insol., the sol. part equally org. and inorg. With a ration of alfalfa hay, corn and linseed meal, lambs secrete in urine 0.2-0.5% of total ingested P. A large part of the acid-insol. P in feeds is changed to acid-sol. and the acid-sol. org. P to acid-sol. inorg. in the feces. The feces contain a large proportion of the acid-sol. inorg. P and little insol. P. The normal P requirement of lambs does not exceed 3 g. per day per 100 lbs. live wt. No relation is shown between P retained by the body, the P ingested, the protein ingested or the body wt. of lambs. On varying the digestible protein in feed from 1.56 to 3.19 lbs. per 1000 lbs. live wt. per day there was no appreciable influence on the forms of P in the feces, the total P in the urine, or the total P stored in the animal body.

R. O. E. DAVIS.

The value of dry yeast, potato vinasse, malt sprouts and palm seed cake under various conditions as feedstuffs for milk production. Specific actions of said feedstuffs on the fat content of milk. W. VÖLTZ, A. BAUDREXEL AND W. DIETRICH. *Landw. Jahrb.* 47, 573-638(1914).—The results of expts. carried out on four cows for two successive years are summed up as follows: Malt sprouts increased the milk yield but not its fat content and therefore they should be fed (as a component of mixed feed) when the milk is to be valued according to measure rather than fat content. Palm seed cake increased the fat content considerably, as G. Kühn, v. Knieriem, v. Lochow, Hansen, and others, have found. Yeast also increased the fat content of the milk but not to as great an extent as the palm cake. The potato vinasse had a slight negative influence on % of fat.

C. F. MILLER.

A contribution to the study of the amine-acid content of the blood. PAUL GYÖRGY AND EDGARD ZUNZ. Univ. Brussels. *J. Biol. Chem.* 21, 511-37(1915).—Dogs weighing from 7 to 10 kg. were bled from the carotid artery after fasting 24 hrs., during which time they were allowed to drink water freely. Part of the blood was centrifuged and alc. exts. were made of the whole blood and of the plasma according to the method of Van Slyke and Meyer. The urea was removed by the action of urease and the soln. freed from NH_3 by Folin's method. The amino-N content was then detd. by the micro-method of Van Slyke. The relative vol. of corpuscles and plasma was detd. by means of the hematocrite of Kottmann. The blood during fasting and in normal conditions contains from 4 to 5 mg. of amino-N per 100 cc. and the amt. is remarkably const. for both corpuscles and plasma. There is an increase in amino-N content of

about 38% about 4 hrs. after copious bleeding. This increase is prevented if Ringer soln. is injected intravenously during the bleeding. During the digestion of a meal poor in protein, such as purée of potatoes, there is no appreciable change in the amino-N content of the blood. An increase of 2-3 times the normal amt. follows the ingestion of meat, the increase being greater in the corpuscles than in the plasma. If the dogs are bled before the meat is eaten, the increase is greater than in animals not bled before feeding. The amino-N content of the blood taken 4 hrs. after the ingestion of meat has a const. value of from 10 to 12 mg. per 100 cc., an increase of 148%. During the digestion of a meal rich in protein, the amino-N content of venous blood is lower than that of arterial blood, indicating a retention of aminoacids by the tissues during digestion.

A. P. LOTHROP.

The significance of glycogen and starch as intermediate products in the metabolism of certain organisms. H. I. WATERMAN. Dordrecht. *Chem. Weekblad* 12, 552-6 (1915).—When *Aspergillus niger* is cultivated under favorable conditions on a sugar soln. there are formed a new mold material, CO₂, water, and other products. There does not appear to be a proportionality between the amt. of mold material and CO₂ formed and the amt. of sugar taken up. Euler has observed in the case of alc. fermentation that the amt. of sugar taken up by the yeast is not proportional to the CO₂ evolved. This is explained by noting that two main reactions take place: (1) The formation of intermediate products from sugars, and (2) the decompn. of these into sugars, and then into CO₂, alc., etc. Of these intermediate products starch is important in plants and glycogen in animal organisms. W. has studied the decompn. reaction of the starch in bananas. When dried at a low temp. (35-60°) a certain % of the starch is converted first to sugar, and then to further decompn. products. The bananas including the skin were sliced and 3 portions dried at different temps., powdered and analyzed. Invert and cane sugar were estd. by extn. with water and measurement of the opt. rotation and reducing action of Fehling soln., before and after inversion. The starch was detd. in the residue after extn. of the sugar by alc. Drying at 60° brings about considerable conversion of the starch into sugar. The starch content of the powder dried at 105° was 7.3%, of that dried at 60° 1 % lower, while the total sugar content of the latter was 1.4% higher. The sugar content of the material dried at 45° was abnormally low (3.8%), much lower than of the product dried at 105°, due probably to a further decompn. of the saccharose or invert sugar with the loss of CO₂.

ABNORMAL.

Albumin milk in infant feeding. V. POULSEN. *Ugeskrift for Læger* 77, No. 21(1915); *J. Am. Med. Assoc.* 40, 372.—Observations with 85 infants under 1 year failed to show advantages of feeding albumin milk in cases of acute gastro-enteritis. In chronic dyspepsia albumin milk proved to be more beneficial than any other measure. The change to other food should be made very gradually. With 29 children, from 1 to 5 years old, suffering from chronic dyspepsia, albumin milk as a supplement to other food gave strikingly good results in every case.

ANDREW HUNTER.

Hydrogen ion concentration in blood under various abnormal conditions. M. L. MENTEN AND G. W. CRILE. *Am. J. Physiol.* 38, 225-32(1915).—H⁺ conc. may be markedly increased in the blood in some abnormal conditions, e. g., during fright or anger (due probably to increased CO₂ tension), in anesthesia by Et₂O, CHCl₃, or N₂O, and in shock. Blood flowing from the adrenal glands is always more alkaline than venous blood of the general circulation, due probably to the base epinephrine in the blood of the adrenal vein.

J. F. LYMAN.

Effect of various mechanical conditions on the gaseous metabolism and efficiency of the mammalian heart. C. L. EVANS AND Y. MATSUOKA. *J. Physiol.* 49, 378-405 (1915).—Work of the heart, using the heart-lung prep., was calcd. assuming 1 cc. O = 3.4 cal. or 2.07 kg.-m. In calcg. work of the heart the velocity factor must be considered, as with high outputs it may account for 5% of the total work. With increased pressure gaseous metabolism is increased and mechanical efficiency raised up to a certain limit, beyond which it is diminished. With increased output metabolism is increased to a max., falling off again with further increase of output. Increase of output is more economically accomplished than a comparable increase of pressure. A parallel is usually demonstrable between O usage and heart vol. J. F. LYMAN.

G. PATHOLOGY.

H. GIDEON WELLS.

The diagnosis and significance of gastric hyperacidity. F. W. ROLPH. Univ. Toronto. *Quart. J. Med.* 8, 309-16(1915).—The symptoms of hyperacidity depend on the H-ion content. Therefore small amts. of ionized combinations are more harmful than larger amts. of less ionized combinations. The hydrolysis of protein liberates groupings whose combinations with HCl are more ionized than the combination of the protein itself with the acid. Whatever the true explanation of the hyperacidity in disturbances of gastric function may be, the symptoms of hyperacidity go with a conc. of H ions in the gastric contents after a test meal which is indicated by a reaction with tropaeolinoo, and the reaction is never given when the symptoms are absent. The presence or absence of this degree of acidity cannot be detd. by titrating the amt. of acid that gives the reaction to Töpfer's reagent. JOHN T. MYERS.

The properties of urine of patients with frozen feet. L. TIXIER. *Union pharm.*, June, 1915; *Repert. pharm.* 27, 173-4(1915).—The ratio of NH₃ to urea which is normally 1:40 varied according to density between 1:8 and 1:30. The reaction to litmus was alk. The urine contained neither albumin nor sugar but appreciable amts. of indole and skatole were detected. Millon's reagent gave a ppt. of protein compds. varying in color from pale pink to red. A microscopic exam. showed the presence of crystals of MgNH₄PO₄ and of tyrosine and cystine. These symptoms indicate the presence of acid amides and point to a diminution in intraorganic oxidation. H. L. OLIN.

Multi-pollen vaccines in the treatment of hay fever. HENRI ISKOWITZ. *Med. Record* 88, 270-2(1915). A. H. RAHE.

Protein absorption as a factor in the causation of cancer. J. WALLACE BEVERIDGE. *N. Y. Med. J.* 102, 387-90(1915).—End products of protein digestion may reach the general circulation through intestinal lesions and if they are present in quantities greater than the liver can deal with, toxic effects may ensue. A. H. RAHE.

Pathologic liquids of chylous appearance. I. Pleural chyiform discharges. G. PATEIN. *J. pharm. chim.* 11, 265-71(1915).—Two examples of such liquids are cited (M. Khouri, 1898, and C. A. 9, 1200). P. gives analyses of 3 similar liquids removed from the chest of a tuberculous patient at different periods. The first, amounting to 1 liter, was milky, slightly yellowish, free from pus, of alk. reaction, d. 1.025, in g. per l., total solids 85.8, mineral matter 9.5, fatty matter 2.0. The second, 500 cc., was greenish gray, thick, milky, very alk., d. 1.021, in g. per l., total solids 64.5, mineral matter 9.6, fatty matter 8.4, and showed pus and fatty granules. In both liquids were traces of reducing and biliary matters, no fibrin, no fibrinogen. The 3rd liquid was also purulent, greenish yellow, alk., d. 1.022, total solids 69.5, mineral matters 8.2, albuminoids 42.5, fatty matter 14.8, consisting of free fatty acids 11.2, fatty acids combined as soap 3.6 g. per liter. Reducing and biliary matters, fibrin and fibrinogen were absent. The fatty matter also contained a small amt. of cholesterol and notable

amts. of lecithin. The m. p. of the fatty substance is much higher than that of the fatty matters from ascitic liquids or chyliform urine, and may exceed 80°. The albuminous matter in the 3rd liquid is nearly all pptd. by adding 10 vols. of H₂O and rendering faintly acid with AcOH. The ppt. contains no much, but nucleoproteins abundantly.

S. WALDBOTT.

The significance of the distribution of urea in the body. D. M. DAVIS. Johns Hopkins Univ. *Bull. Johns Hopkins Hosp.* 26, 154-5 (1915).—The urea content of all organs and tissues is approx. uniform and equal to that of the blood, with the exception of fat which has a low content and the urinary tract which has a high urea content. The retention of urea commonly observed in nephritis may be a mechanism whereby the injured kidneys are stimulated by the diuretic action of the urea until they are able to eliminate an amt. equal to the daily production. It is difficult to interpret the significance of the urea content of the blood in any case on account of the innumerable kinds of nephritis, in each of which the excretion of different substances is affected differently. "The quantity of urea in the blood of a patient at any moment can naturally give much less information than a study extending over some time, and including as many factors as possible, i. e., blood detns., urine detns., diet and other methods of estg. renal function."

A. P. LOTHROP.

An abnormal yellow pigment in urine. ED. JUSTIN-MUELLER. *J. pharm. chim.* 12, 57-9 (1915).—The urine in a case of pneumonia followed by purulent pleurisy was feebly acid, contained 1.03 g. dextrose and 0.35 g. albumin per l., and urobilin in notable amt. The color was reddish yellow, but did not stain filter paper nor did it give a colored foam. Alkalies, especially NH₄OH, turned it an intense yellow which stained filter paper and gave color to foam. Upon defecating the original (acid) urine with Pb subacetate and filtering, the ppt. is chamois-yellow but the filtrate is decidedly yellow and stains filter paper yellow. It proved to be free from urobilin. The chromogen could not be extd. by org. solvents. It disappears upon acidulating. The urine does not resemble icteric urine nor does it give Grimbart's test for bile pigments. The defecated urine (removing Pb by Na₂SO₄) shows special absorption bands between 135 and 160, urobilin in CHCl₃ soln. between 120 and 140. The bands were not shown by non-defecated urine whether alk. or not. The pigment is probably due to an alteration in the liver.

Behavior of the isolated heart of the frog under the action of nicotine and heat. GIOVANNI B. ZANDA. Univ. Genoa. *Arch. farm. sper.* 19, 505-10 (1915).—Heat and nicotine produce opposite effects when applied separately, the former accelerating and the latter retarding the heart beat. However, neither one counteracts the effect of the other. Heat tends to exaggerate the effect of the nicotine, no matter whether the heat or the nicotine is applied first.

A. W. DOX.

Observations on plasmapheresis. B. B. TURNER, E. K. MARSHALL, JR. and PAUL D. LAMSON. Baltimore. *J. Pharmacol.* 7, 129-35 (1915).—Plasmapheresis may be carried on to a greater extent than was indicated by earlier work; in dogs 4 to 5 times the vol. of blood has been withdrawn in 4 to 5 days successfully, death resulting from intercurrent infection in some cases, in others from toxic effects of a particular variety of hirudin. The blood pressure falls with the repeated bleedings, but this can be remedied. The number of red corpuscles rises, that of white cells falls in plasmapheresis during a day's work, with a reverse change at night. No destruction of corpuscles has been demonstrated. There is also a decrease of protein in the plasma to about 1/3 of its original value, caused by 3 days plasmapheresis; this is followed by a slight increase. Urea and total non-protein-N increased from the beginning.

A rise in temp. by 1° was observed during each day of plasmapheresis with a return to normal during the night.

P. J. HANZLIK.

The role of the liver in acute polycythemia. A mechanism for the regulation of the red corpuscle content of the blood. PAUL D. LAMSON. Baltimore. *J. Pharmacol.* 7, 169-224(1915).—The author's own condensed summary brings out the important points of his lengthy paper: (1) The red corpuscle content of the blood is a constantly varying quantity under physiological conditions. (2) Certain new means have been found by which the red (corpuscle) count may be rapidly and greatly increased: (a) lung emboli produced by the injection of corpuscles hardened with HCHO, of an inert powder, as lycopodium, or of oil; (b) emotional stimuli, as fright or rage. (3) The polycythemia produced by injection of epinephrine is due to the action of the liver alone. (4) Ligation of the arterial blood supply to the liver excludes the production of polycythemia after the injection of epinephrine. (5) Later release of this ligation allows the customary increase in number of red cells to take place, without the further injection of epinephrine. (6) The liver effects this increase in number of red cells by (a) a decrease in plasma vol. (not sufficient to account for the entire increase in the number of red cells, however); (b) by bringing into the circulation red cells which were not present before the production of polycythemia as shown by (a) their reduced size, (b) their reduced % hemoglobin content. (7) These cells give none of the usual reactions of young cells. There is an absence of nucleated red cells, no change in the fragility of the corpuscles, and no increased metabolism of the red cells themselves, as shown by an increased rate of reduction. (8) It is concluded that there is a mechanism for the regulation of the red corpuscle content of the blood; (9) that the regulatory mechanism is under nervous control, reacting to lack of O as a stimulus; (10) that the adrenal glands play a part in this mechanism; (10) that the liver is the organ which supplies the body with red cells to meet its acute demands.

P. J. HANZLIK.

The action of oxycholine derivatives on purine metabolism and their therapeutic application. T. BURGSCHE AND R. WOLFFENSTEIN. Berlin. *Berl. klin. Wochschr.* 52, 157-9(1915).—On the basis of the work of Nicolaier and Dohrn who suggested the use of atophan (2-phenylquinoline-4-carboxylic acid) in the therapy of gout, B. and W. make a study of certain synthetic substances using the quinoline ring as a nucleus. 1-Hydroxyquinoline (a) is found to increase the excretion of allantoin in dogs and uric acid in man. This only happens if the liver has a high content of purine compds. When the liver has been exhausted there is a decrease in the excretion of these substances. The toxicity of (a) prevents its therapeutic application. Its salicylate increases the excretion of uric acid and also inhibits the formation of uric acid. Because of these properties and of its non-toxicity, it is recommended in the treatment of gout.

JULIAN H. LEWIS.

The biological action of condensed radium emanations. E. PARTOS. Stuttgart. *Berl. klin. Wochschr.* 52, 181-3(1915).—The first decompn. product of Ra is an inactive gas called "emanation" which can be condensed at -155° . The authors detd. the effect of this substance on mice. If exposed long enough to the condensed gas mice are killed. In smaller doses the chief effect is on the spleen. The leucocytes in this organ are destroyed and the connective tissue takes on a hyaline appearance. Besides these changes there was also produced acute parenchymatous nephritis and severe burns of the skin.

JULIAN H. LEWIS.

Spinal anesthesia in the cat. G. G. SMITH AND W. T. PORTER. *Am. J. Physiol.* 38, 108-27(1915).—Expts. are reported which show the effects under various conditions of novocaine and tropacocaine on blood pressure and respiration.

J. F. LYMAN,

Perfusion of the mammalian medulla. Effect of calcium and potassium on the respiratory and cardiac centers. D. R. HOOKER. *Am. J. Physiol.* 38, 200-8(1915).—When the medulla of the dog is isolated and perfused with solutions containing washed blood corpuscles the respiratory center is stimulated and heart rate increased by a preponderance of Ca^{++} over K^+ . Conversely when K^+ predominates over Ca^{++} the respiratory center is inhibited and the heart rate decreased. After cutting the accelerator nerves, K^+ increase causes pronounced cardiac slowing, while Ca^{++} increase causes slight cardiac acceleration. When the vagi are cut, Ca^{++} causes a definite cardiac acceleration and augmentation while K^+ causes a slight cardiac slowing.

J. F. LYMAN.

Mode of action of carbon dioxide on blood pressure. E. P. CATHCART AND G. H. CLARK. *J. Physiol.* 49, 301-9(1915).—The rise of blood pressure following administration of small amounts of CO_2 to the intact animal is not obtained (1) after decapitation, (2) after injection of nicotine. It is concluded that the action of CO_2 upon the adrenals and blood pressure is exerted through the agency of some central mechanism.

J. F. LYMAN.

Absorption of drugs from the nasal submucosa of dogs. J. D. PILCHER. *Omaha J. Am. Med. Assoc.* 40, 232-4(1915).—In a previous paper (*J. Am. Med. Assoc.* 38, 209(1915)) P. showed that epinephrine injected into the submucosa of the nasal turbinates of dogs, was absorbed with a rapidity approx. that of an intravenous injection. In this article the results are given of similar expts. with histamine, tyramine, *Veratrum viride*, nitrites, KI, CHCl_3 , strophanthus and methylene blue. All but the last three were quite rapidly absorbed when administered by this method as compared to controls injected intravenously.

Recent advances in the relation between chemical structure and pharmacological action. J. M. FORTESCUE-BRICKDALE. *Bristol Royal Infirmary. Brit. Med. J.* 1915, I, 106-7.

M. RINGER.

Coagulation time of blood. VII. Influence of certain anesthetics. W. L. MENDENHALL. *Am. J. Physiol.* 38, 31-51(1915).—If CHCl_3 and chloral hydrate affect the coagulation time at all they prolong it. The mechanism of action is not apparent; the production of a retarding agent is not proved. Et_2O hastens coagulation. This is due wholly to its action on the adrenals with the subsequent pouring out of epinephrine and its accelerating effect on coagulation.

J. F. LYMAN.

Saline diuresis. S. YAGI AND K. KURODA. *J. Physiol.* 49, 162-70(1915).—When mixts. of NaCl and Na_2SO_4 are introduced intravenously and diuresis limited by compression of the renal artery on one side the vol. of urine and amts. of NaCl and Na_2SO_4 are reduced, while the % of NaCl is lower and of Na_2SO_4 higher on the compressed side. With NaCl and urea results are similar except that % of both NaCl and urea are higher on the compressed side. Lowering of blood pressure by stimulation of the vagus affects the excretion of Cl, SO_4 and urea in the same way as does compression of the renal artery.

J. F. LYMAN.

The deposition of arsenic in hair. A. HEFFNER. *Verhandl. Jahresschr. ger. Med.* 49, 194-205(1915).—As and organic As compds. are capable of being absorbed by the hair of a living but not of a dead person. The As content of the hair varies in man from 1 to 5 in 100,000. The deposition in the hair takes place later than in the organs of the abdominal cavity (liver, kidney). In the case of quick, acute poisoning, these organs contain As, but not the hair. For legal medicine the exam. of the hair for As poisoning is important. If the hair contains As and all other organs do not it may be concluded that there have been As absorptions, but not recently. Exam. of the hair for As on a living person can either prove or disprove the suspicion of chronic As poisoning.

E. J. KELLEY.

Demonstration of salvarsan in forensic cases. G. MÜLLER. *Vierteljahreschr. ger. Med.* 49, 48-74(1915).—These expts. were conducted in connection with a case of suicide by strychnine poisoning in which the action of salvarsan came into question. Salvarsan was found in the urine 37 hrs. after injection. It was also shown to be present after injection, for a period of 9 days in the liver, and 12 days in the muscles. An insignificant sublethal dose of strychnine is sufficient to cause a reaction in salvarsan-treated animals.

EDWARD J. KELLEY.

Therapeutics and chemistry of the oxypimenes (BLOMÉN) 17.

12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

The amino-acid content of certain commercial feeding stuffs and other sources of protein. E. H. NOLLAU. Kentucky Agr. Expt. Sta. *J. Biol. Chem.* 21, 611-4 (1915).—N distribution in 22 com. feeding stuffs and other protein substances was detd. by the Van Slyke method. Histidine was absent from distillers' dried grains and cowpea; non-amino-N from wheat bran and maize kernel; lysine from rice, oat grain, rolled oats and barley. Soy bean, distillers' dried grains, wheat bran, dried blood, maize kernel, hemp seed and sunflower seed contain relatively large amts. of lysine. Monoamino acids constitute, in most cases, one-half of the amino acids present. The peanut, black walnut and hickory nut contain much arginine, the pecan little. The reverse is true of the histidine content. Gluten and gluten flour have a high NH₂ and a low lysine content.

A. P. LOTHROP.

Modification of the constituents of flour which occurs during baking. Chemical composition of bread. H. KALNING AND A. SCHLEIMER. Berlin. *Z. ges. Getreidew.* 6, 137-43(1914).—The differences in compn. of crust and crumb are principally due to differences in temp. (95-100° in the center of the loaf and 180-200° at the surface) during baking. K. and S. have investigated these differences, as well as the differences in compn. of flour and bread. The baked products were of the usual rounded form and weighed approx. 1500 g. each; 2 types were compared, 1 with light and the other with dark crust. Three kinds of wheat bread (sour dough bread from 30-70 wheat flour and bread from 0-30 and 30-70 wheat flour with yeast) and 2 kinds of rye bread (sour dough bread from 0-65 rye flour and bread with yeast from 0-65 rye flour) were prepd. The ash, protein, fat, crude fiber and N-free ext. contents of the crumb and crust (both light and dark) of these types of bread, as well as the flour from which the bread was made, were detd. No appreciable differences were observed in the contents of these substances in crumb and light and dark crust; differences

(except in the case of crude fiber) were observed, however, when the compn. of the crumb and crust of the bread was compared with that of the corresponding flour. The carbohydrate content of the bread was diminished because of losses during fermentation, while the greater ash content of the bread was due to addition of NaCl. The increase in the fat and protein contents of the baked products is due to the fat and protein content of the yeast. The glucose, maltose, invert sugar, dextrin and ext. (residue after evapn.) contents of the H₂O exts. of flour, crumb and crust (light and dark) were next compared. No definite conclusions were derived in so far as the sugars were concerned; a slight decrease in the sugar content of the wheat bread as compared with the flour was observed, while for rye bread, the sugar content either increased considerably or remained unchanged (especially in the crumb) as compared with the flour. With the exception of the yeast rye bread a considerable increase in dextrin and ext. contents was observed in the crust as compared with the crumb; this increase is due to dextrinization of the starch in the crust by the action of H₂O vapor at the high temp. of the exterior of the loaf. The 8% excess of dextrin in the crumb, as compared with the crust, of the yeast rye bread was probably due to formation (by enzymes of the yeast) from the starch of compds. which were transformed by further increase in temp. into H₂O-insol. substances; such action would be in accord with the observed smaller H₂O-ext. content of the dark crust as compared with that of the crumb. The rye flour showed considerably smaller contents of dextrin and H₂O-ext. than did the bread; this difference was due to the influence of temp. in baking. The soln. obtained by H₂O-extn. of the crumb gave (after filtration) a reddish brown coloration (maltodextrins) with I in KI soln., while the soln. from the crust gave a blue coloration (corresponding solns. from the dough and flour gave no coloration with I). The reaction of the ext. of the crust was due to sol. starch which was formed by the action of H₂O at the high temp. of the exterior of the loaf, while the temp. at the interior of the loaf was not high enough to produce this result. The analytical data indicate considerable dextrinization of starch in the crust (the dark crust of the wheat breads contained 2-3 times as much dextrin as the crumb). These results are not in accord, however, with the results of the starch detns. (by the Ewers method) which indicate practically the same starch content in crumb and light and dark crust; this discrepancy is doubtless due to the fact that dextrins are hydrolyzed by the Ewers method and are hence calcd. as starch. The fact that the flour had a higher starch content than the bread is due to the action of the diastase of the flour on the starch; a corresponding increase in the total sugar content of the bread was not observed, inasmuch as a portion of the sugar was destroyed by enzymic action. The H₂O-sol. and alc.-sol. (55% alc. by wt.) proteins of flour, crumb and crust (light and dark) were detd. after 2 hrs. extn. In almost all cases the sol. protein content of the crust was less than that of the crumb. This decrease is attributed to greater coagulation at higher temps.; for the same reason the bread as a whole showed a smaller content of sol. protein than did the corresponding flour. No appreciable differences in content of total or H₂O-sol. P₂O₅ were observed when flour and bread (crumb and light and dark crust) were compared; this indicates that no change in the mode of combination of P₂O₅ occurred during baking. It is also probable that the P₂O₅ is not combined to any great extent with proteins, since in this case the solubility of P₂O₅ in combination would be expected to vary with the temp. The above results show that the principal difference in the compn. of crumb and crust is due to the influence of increased temp. on carbohydrates.

H. S. PAINE.

Sucrose and invert sugar as partial substitutes for flour in bread making. JOHANN JELINEK. Prague. *Z. Zuckerind. Böhmen* 39, 281-3(1915).—The regulations governing bread making in Austria permit the substitution of sugar for rye and wheat flour in an amt. not exceeding 5%; in view of the tax on sucrose, J. proposes to employ the

less expensive invert sugar for this purpose. In a 1st series of expts. bread was made from flour containing 5% sucrose and 6.25% invert sugar sirup, resp.; yields of 137% and 149% bread were obtained. The loaves made by use of invert sugar were more rounded than those made with sucrose; the difference in porosity and tenacity of crumb was slight. The dough was salted normally in the prep. of the bread, but the salt taste was partly concealed by the presence of sugar, so that the bread tasted as though it had not been salted sufficiently. The bread made by use of sucrose appeared to be somewhat sweeter than that made with invert sugar, although the difference was very slight; the latter bread had, on the whole, a more agreeable taste. In a 2nd series of expts. (performed on a larger scale in a bakery) bread was made in the following manner: (1) without addition of saccharine material; (2) with addition of 5% sucrose; (3) with addition of 6.25% of 80% invert sugar syrup (prepd. by heating for $\frac{1}{4}$ hr. at 95° a soln. of 1 kg. sucrose in 240 cc. H_2O with addition of 0.5 cc. 36% HCl and 9.5 cc. H_2O); (4) with addition of 6.25% of 80% invert sugar syrup (prepd. as in case of (3) except that the period of heating was $1\frac{1}{2}$ hr.). The yields of dough were 155, 150, 160 and 156%, resp.; the increased yield in the case of the light colored invert sugar syrup (No. 3 above) was probably due to the fact that this sugar is most readily assimilated by the microorganisms during fermentation of the dough. The tenacity of the crumb was practically the same in all 4 cases. The bread made by use of sucrose had the smallest pores and was solid and compact, while that made by use of light colored invert sugar syrup (No. 3) had the most pores. A greater amt. of NaCl was added to the dough in these expts. so that the taste of sugar was not so pronounced as in the 1st expts. The bread made by use of light colored invert sugar syrup had the most agreeable flavor in both series of expts. The increase in tenacity of the crumb on becoming stale was most pronounced in the case of bread made without addition of saccharine material. It is concluded from these observations that the addition of invert sugar to the dough in bread making is more advantageous than addition of sucrose. Inasmuch as 0.5-1.0% NaCl must be added to the dough, the required amt. (10-20% in the case of the addition of 6.25% syrup) may be added to the invert sugar syrup so that the latter is thereby denatured and rendered unfit for almost all other purposes.

H. S. PAINE.

Concealing the use of blood in bread. R. DROST. Hanover. *Chem. Ztg.* 39, 634(1915).—The use of blood in bread may be concealed by keeping the blood in a refrigerator for 24-35 hrs., then filtering off the serum and using it to make the dough to which H_2O_2 is added instead of yeast or baking powder. The liberated O raises and bleaches the bread. Cf. Kobert, C. A. 9, 1951.

J. H. MOORE.

Studies on the expansion of milk and cream. H. W. BEARCE. *J. Agr. Res.* 3, 251-68(1914).—In order to det. the change in vol. of milk and cream which occurs with variations in the temp., so that accurate allowance can be made in making measurements by vol. at high temps., sp. gr. detns. were made over a range of from 0° to 50° and with samples in which the fat content varied from 0.025 to 40%. Having detd. the d. of each sample and the rate of change of d. with change of temp., 20° was adopted as the standard temp. and a table was prepd. giving the vol. of all samples at all temps. calcd. in terms of the vol. at 20° . The results, though sufficiently accurate for the purpose for which the investigation was undertaken, revealed certain anomalies which made it appear that the rate of expansion of any given sample depends on something more than the d. or the % of fat present, viz., on the chem. and phys. condition of the sample, which are largely controlled by the time that has elapsed since the prepn. of the sample, and upon the temp. at which it has been kept.

Adulteration of butter by addition of coconut oil. RENÉ LEDENT. Liège. *Bull. soc. chim. belg.* 27, 325-30(1913).—In the exam. of pure butter obtained from the

milk of cows receiving a daily ration which included coconut press-cake certain investigators have observed values for physical and chem. indexes which justify the conclusion that the butter had been adulterated with coconut oil; certain crystallographic characteristics described by Césaro as sp. for coconut oil were also observed. In view of the doubt attached to the validity of the accepted physical and chem. indexes in these instances L. has analyzed (detn. of d., n , the indexes of Crismer, Meissl, Polenske, Wauters and Hehner, the index of sapon. and the I no., as well as exam. by the Césaro method) the pure butter of cows which were fed beet leaves, as well as beet leaves and coconut press-cake. The analytical data clearly indicate the presence of coconut oil in the butter of the cows which were fed coconut press-cake: The Polenske index showed a deviation in content of insol. volatile acids from the accepted values for pure butter; an increase was observed in this respect, while the content of sol., volatile acids decreased (with a corresponding increase for the butter of the cows which only received a ration of beet leaves). An increase in the index of sapon. and a decrease in the I no. were also observed for the butter of the cows which were fed coconut press-cake. A number of the samples examd. were somewhat rancid; the values of the Crismer index are given without correction so as to show the degree of rancidity. After alc. extn. according to the Césaro method not one of the samples yielded an ext. which presented the characteristics of coconut oil when examd. microscopically by means of polarized light. Two extns. were made for each sample, one with 80% and the other with 90% alc. (both extns. continued 1 hr. at 35-37°). In filtering the alc. soln. care was taken to leave in the extn. flask the felt-like mass (almost exclusively butter) which adhered to the wall of the latter. In order to detect with certainty the presence of coconut oil, when the latter is added to butter in the proportion of 5%, L. suggests that the conc. of the alc. be reduced to 60%; the amt. of dissolved butter glycerides would be thereby decreased, while the content of coconut oil glycerides in the alc. ext. would be increased.

H. S. PAINE.

Is it hygienic to use apricot and peach kernels in the preparation of marchpane? K. B. LEHMANN. Würzburg. *Chem. Ztg.* 39, 573-5(1915).—L. compares the amt. of bitter principle in these kernels with several varieties of almond and concludes that if they are properly treated for several hrs. with H_2O at 50° to reduce the benzaldehyde below 40 mg. in 100 parts they may safely be substituted for almond. J. H. MOORE.

The international movement of feeding stuffs. ANON. *Bull. Agr. Intelligence* 6, 481-516(1915).—This is the first of the annual reviews on this subject that are to be published by the Intern. Inst. of Agriculture. A large amt. of data on production, trade, consumption, etc., of the various feeding stuffs is given, the data for each country being treated separately. A 6-page bibliography is appended.

Brit., 10,774, May 1, 1914. P. A. DOCHERTY. Yeast for baking purposes is treated to remove bitterness by washing with H_2O to remove sol. and heavy impurities, treating with a weakly alk. soln. such as $(\text{NH}_4)_2\text{CO}_3$ soln., and allowing it to stand for some time in contact with wood charcoal.

14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW.

Stripping water works reservoirs. F. P. STEARNS. *Eng. News* 74, 302-4(1915).—The object of stripping is to diminish the food supply of microorganisms which cause taste or odors. Water reservoirs should improve with age. A clean bottom prevents unloading of decomposing material by vertical circulation. LANGDON PEARSE.

Water softening by the permutite system. C. P. HOOVER AND R. D. SCOTT. *Ohio Pub. Health J.* 6, 143-50(1915).—At Columbus a comparison of the $\text{CaO-Na}_2\text{CO}_3$ method with the permutite method was undertaken with the following results: (1) cost of operation with permutite was higher than with $\text{CaO-Na}_2\text{CO}_3$, the $\text{CaO-Na}_2\text{CO}_3$ costing \$4.75 per mil. gal. for removal of 100 pts. of hardness as compared with \$8.61 for permutite. (2) Permutite-softened H_2O contains residual NaHCO_3 which may cause trouble in boilers. (3) Permutite is the only substance which gives a zero-hard H_2O , the variations in the hardness of raw H_2O being automatically taken care of. (4) There is no sludge to be removed in the permutite process, but the water should be clear, for a turbid H_2O clogs and thereby impairs the process. J. GAUB.

The disinfection of water. W. H. DITTOE. *Ohio Pub. Health J.* 6, 133-42(1915).—D. discusses the effect and methods of use of the following agents: (1) Heat, (2) Cu salts, (3) permanganates, (4) O_3 , (5) Cl_2 and $\text{Ca}(\text{OCl})_2$, (6) CaO , (7) ultraviolet light. J. GAUB.

Bureaus of water supplies. E. BARTOW. *Am. J. Pub. Health* 5, 871-4(1915).—B. points out the importance of state bureaus together with a national bureau which should coöperate with the state bureaus, especially in interstate questions. J. GAUB.

Six years of softened and purified water at McKeesport, Pa. E. C. TRAX. *Eng. Contrg.* 44, 137-8(1915); cf. C. A. 8, 3831.—The water from the Youghiogheny River has an acidity of over 3 grains per gal. at times, varying from an alkalinity of 40 pts. per mil. to an acidity of 390 pts. per mil. and a hardness of 200 pts. per mil. Softening with lime and soda has made a water palatable and safe, the typhoid being markedly reduced.

Relative stabilities in polluted waters carrying colloids. A. LEDERER. *Am. J. Pub. Health* 5, 740-3(1915); cf. C. A. 8, 3337.—L. thinks it useless to det. relative

stabilities in turbid H_2O by the methylene blue test. To obtain correct O_2 demand the following method should be followed: Det. free O_2 on the spot and add $CHCl_3$ to a sample for NO_2 and NO_3 detn. Then take 3 other samples; to 1 of these add a definite amt. of saltpeter or H_2O free from NO_2 and NO_3 but of known O_2 content. The other two remain as collected. All of these samples are incubated in closed bottles for 10 days at 20° . At the end of this incubation the residual available O_2 is detd. in samples devoid of additional H_2O or saltpeter. The other sample is examd. for NO_2 and NO_3 . If free O_2 remains after incubation the residual saltpeter O_2 need not be detd. The initial available O_2 minus the residual gives the biochem. demand. In badly polluted waters, free O_2 need not be detd. because it will be absent after incubation. Generally, NO_2 and NO_3 are attacked when free O_2 is reduced about 50%. J. GAUB.

A study of methods of sewage disposal in industrial and rural communities and suggestions for their improvement. J. F. SILER, P. E. GARRISON AND W. J. MACNEAL. *Am. J. Pub. Health* 5, 820-32 (1915).—The methods of disposal of excreta as practised in the South are reviewed. The authors think that benefit to a community is possible by the installation of complete water systems and sewage disposal plants. The expense would vary from \$210 to \$265 per house. J. GAUB.

Notes on the practical application of the saltpeter method for determining the strength of sewages. A. LEDGER. *Am. J. Pub. Health* 5, 354-61 (1915).—For sewages: Use a soln. contg. 26.56 g. $NaNO_3$ per l.; 1 cc. of this equals 50 pts. per mil. when in 250 cc. of sewage. Incubate the sewage containing the saltpeter for 10 days at 20° . The appearance of a black sediment and the development of a putrid odor during incubation show that too little saltpeter has been added. Methylene blue may be used as an indicator. Decolorization indicates presence of too little saltpeter. At the end of the incubation, det. NO_2 and NO_3 . Change the N_2 to O_2 equivalents by multiplying NO_2 by 1.7 and the NO_3 by 2.9. The initial available O_2 minus the residual O_2 gives the biochem. O_2 demand. For trade wastes the same procedure is used with larger amts. of saltpeter. Neutralize an acid waste with $NaHCO_3$ or a too alk. one with dil. HCl . Also inoculate a sterile one with sewage after adjusting the reaction. In the case of filter effluents this method may be supplanted by Phelps relative stabilities, provided no colloidal matter is present, and the initial available O_2 is detd. When clay and other colloidal matter is present, 2 samples must be incubated, one for residual free O_2 and the other for residual NO_2 and NO_3 . J. GAUB.

Seven years' experience with a large sludge pressing plant. JOHN T. THOMPSON. *Surveyor* 48, 100-3 (1915).—Sewage is pptd. with 10-100 p.p.m. CaO . Milk of lime is added to the sludge to about 1%. Oiling the press cloths for 8 in. all around the outside, around the center hole, and where the bosses meet lengthened the av. life from 156 pressings to 200 pressings. About one-third of the press cake is given to farmers for manure; the rest is dumped. Cost data are given. W. D. C.

Refuse disposal in southern cities with particular reference to Savannah, Ga., and its new incinerator. E. R. CONANT. *Am. J. Pub. Health* 5, 904-17 (1915).—Southern refuse differs from northern in that it has less grease, more vegetable matter, less ashes and more rubbish; hence the incinerator is used freely. The plant at Savannah is of the Heenan-Froude type and has a daily capacity of 130 tons of mixed refuse. It cost \$126,271 complete and if the refuse delivered to the plant equals the capacity, enough steam will be furnished to operate the pumping station with an annual saving of \$12,000. The clinker varies from 20 to 30% of the total refuse burned. The av. compn. of the refuse is: garbage 45, rubbish 40, ash or cinder 10, manure 5% by wt. The total labor charge per day of 24 hrs. is \$52.50. J. GAUB.

Activated sludge experiments at Baltimore. LESLIE C. FRANK AND CALVIN W. HENDRICK. *Surveyor* 47, 693 (1915).—Proposed schedule of expts. W. D. C.

Toronto sewage disposal plant. C. J. HASTINGS AND R. C. HARRIS. *Can. Eng.* 29, 290(1915).—A report on the sewage disposal situation showed complaints of odor due to poor sludge disposal. Shavings and CaO or $\text{Ca}(\text{OCl})_2$ are used on top of sludge. Expts. showed electrolytic processes and slate beds to be of little value. A brush filter handles 5.5 mil. imp. gal. per acre per day. LANGDON PEARSE.

15. SOILS AND FERTILIZERS.

R. O. E. DAVIS.

Effect of grinding the soil on its reaction as determined by the Veitch method. P. E. BROWN AND H. W. JOHNSON. *J. Ind. Eng. Chem.* 7, 776-7(1915).—If acid soils are ground before being tested by the Veitch method the acidity is reduced and the reaction frequently becomes basic. This development of basicity increases directly with the grinding of the soil and depends upon the amt. of sand present, being greater in coarse sandy soils than in fine soils. B. and J. believe that soils should not be ground previous to testing by the V. method. ISADOR MILLER.

Electrolytic determination of biological soil solution. E. PANTANELLI. *Centr. Bakt. Parasitenk.* 42, 439-43(1914); *Bull. Agr. Intelligence* 6, 663.—In detg. the part played by microbiological action in rendering the soil constituents available, some investigators have measured directly the electrolytic cond. of water-satd. soil; P. modified this method by estg. the cond. of the percolating solns. of the soil. He

used in his expts. different soil samples from the neighborhoods of Tripoli and Naples. Through these he allowed: (a) sterilized water, (b) sterilized water satd. either with CHCl_3 , or 0.5% glucose, or (c) water mixed with glucose and CHCl_3 to percolate 3 times. He found that the detn. of the electrolytic cond. was a good method of estg. the microbiological solubility of the soil particles, especially if the expt. was carried out comparatively with and without the addition of CHCl_3 and glucose. CHCl_3 increases, while glucose decreases, but not always, the leaching out of the salts from the soils. The solubility of the soil usually varies with the number of microorganisms it contains. E. J. C.

Bacteriological investigations of soils. A. VORTKIEVICZ. Moskau. *Centr. Bakt. Parasitenk.*, II Abt. 42, 254-61(1914).—The number of bacteria in the soil varies during the year but not extremely. The max. number occurs in the spring and the minimum number in the winter. The N-assimilation capacity of the soil varies extremely. The minimum comes in the winter and the max. in the fall. In general, there is a parallelism between the number of bacteria and the amt. of N assimilation. The opt. temp. for N-fixation by bacteria changes with the time of year, but somewhat more slowly. The variations of temp. during the day have no influence. Studies on nitrification, putrefaction, ammoniacal decompn. and CO_2 production by soil bacteria gave no certain and satisfactory results. JULIAN H. LEWIS.

Technical application of microorganisms to agriculture. C. E. MARSHALL. Mass. Agr. Coll. *Science* 42, 267-74(1915).—The historical development of the discovery and application of microorganisms in agriculture is traced. R. O. E. D.

New methods in soil protozoology. N. KOPELOFF, H. C. LINT AND D. A. COLEMAN. *Science* 42, 284-6(1915).—The method for counting protozoa is adapted from the well known blood-counting apparatus. A drop of standard size is examd. microscopically. Picrosulfuric acid is recommended for killing and staining the organisms simultaneously. A standard stage micrometer and a soln. of const. depth (1 mm.) are used, so there is no mechanical variation. The method is direct, accurate and rapid. To separate fungi from protozoa a method based on the principle of dilution was devised. From agar plates a cube 2 cm. sq. was cut and in the cavity was placed 1 cc. soil ext. A Pt loop-full of 3-day-old culture of bacteria, protozoa and fungi in soil ext. was rinsed off in the soln. in the cavity. Bacteria and protozoa developed in large quantities but fungi were absent even after 30 days. Comparison of different media for soil protozoa showed that 10% hay infusion is best for small flagellates and 0.5% egg albumen best for ciliates. R. O. E. D.

The scouring lands of Somerset and Warwickshire. C. T. GIMMINGHAM. *J. Agr. Sci.* 6, 328-36(1914).—*Chem. exam.* of the soil of these regions has failed to reveal any substance to which the scouring properties could be attributed. E. J. C.

The biochemical decomposition of nitrogenous substances in soils. W. P. KELLEY. Hawaii Agr. Expt. Sta., *Bull.* 39, 25 pp.(1915).—Studies were conducted on the rate of decompn. of casein, dried blood, soy bean cake meal, cottonseed meal and linseed meal under varying conditions. Ammonification studies were made: In silica sand, in soil, with equal amts. of N supplied, in soil under anaerobic conditions, with equal amts. of nitrogenous and non-nitrogenous materials, with varying amts. of casein, of casein during different lengths of time, of casein in silica sand, and, finally, ammonification and hydrolysis of casein. Casein was decomposed more rapidly than the other substances in silica sand, in soil and when equal amts. of N were provided. As a rule dried blood came next. Casein, with the other substances, was decomposed very slowly, under anaerobic conditions, during the first two days. It then was decomposed almost the same as under aerobic conditions. Other substances decomposed very slowly. In the study of the effects of bacterial action on different groups of N

comps. it was found that in six out of the eight substances used the basic diamino acid N was more readily converted into NH_3 than was the N of other groups. B. E. B.

The international movement of fertilizers. ANON. *Bull. Agr. Intelligence* 6, 323-70(1915); cf. *C. A.* 9, 501.—A thorough compilation of statistics on production, international trade, prices and consumption of P, K and N fertilizers throughout the world. A 6-page bibliography is appended. E. J. C.

Will the loss of lime in the soil be increased by kainite fertilization? GERLACH AND VECKENSTEDT. *Mitt. Kaiser Wilhelm Inst. Landw. Bromberg* 6, 382-93(1915); *Chem. Zentr.* 1915, I, 1137.—Expts. on a loam soil containing 0.38% CaO show that a greater quantity of lime is lost by seepage through a soil fertilized with kainite than through one unfertilized. W. H. FRY.

Is kainite fertilization economic as to water? GERLACH AND SCHIKORRA. *Bromberg. Mitt. Kaiser Wilhelm Inst. Landw. Bromberg* 6, 368-81(1915); *Chem. Zentr.* 1915, I, 1137.—Water evapn. was influenced not at all and absorption of water vapor from the air only slightly by the application of kainite. Water evapn. by the soil and plant jointly is not influenced by kainite so long as the kainite causes no considerable increase of produce. Barley yield was increased in some cases by kainite. In this case the absolute water consumption remained the same, but the relative consumption decreased; kainite is therefore sparing of water. W. H. FRY.

The composition of the coffee berry and its relation to the manuring of a coffee estate. R. D. ANSTEAD. *Annals of Applied Biology* 1, 299-302(1915); *Bull. Agr. Intelligence* 6, 583-4.—Analyses of the berries in different stages of development show preponderance of potash, which remains const. throughout, while the proportion of P_2O_5 attains a max. in the 4th month (October), then steadily declines. Expts. are now in progress to ascertain the precise mineral requirements of this crop and the most suitable stage in which to supply them. Detn. of the H_2O content of the berries shows a steady decrease from July (87.13%) to December (65.77%), but during the final ripening stage in January there is a rise of nearly 1%. This rise in the moisture content would appear to indicate a critical stage in the history of the berry. It may account for the premature falling and failure to ripen of the crop on certain soils and in years of low rainfall. At any rate it suggests changes in the methods of cultivation and manuring so as to develop the root area and conserve the soil moisture. E. J. C.

Absorption of fertilizing substances in different growth phases of the sugar beet. F. CALZOLARI AND G. MASSORRIO. *Boll. assoc. ital. ind.* 7, 201-14(1915); *Bull. Agr. Intelligence* 6, 709.—Analyses of sugar beets were made periodically throughout the growing season from the time when the plants were singled till the crop was mature. It was found that the absorption of fertilizing substances increased continuously throughout growth; N proved the most important constituent at the beginning, and potash at the end of the growing period, while P_2O_5 was almost equally necessary throughout the whole vegetative period. E. J. C.

Results of fertilizer experiments conducted at Summerville, S. Carolina. T. E. KEITT. *South Carolina Sta., Bull.* 178, 20 pp.(1914); *Exp. Sta. Rec.* 32, 423.—The most important fact established is that P is the limiting element in fertilizers for corn and cotton on the soils of this substation. The relative value of different phosphates for supplying this deficiency is discussed; acid phosphate is recommended as most profitable. Org. sources of N were more effective than inorg. E. J. C.

Quassia as a contact insecticide. W. B. PARKER. U. S. Dept. Agr., *Bull.* 165, 8 pp.(1914).—A soln. of quassia (0.4 g. in 2000 cc. H_2O) was successfully used in exterminating the hop aphid (*Phorodon Humuli*, Schrank) and the prune aphid (*Hyalop-*

terus pruni, Fab.) in a moist district in California. 100 gals. of spray cost 24 cents.
E. J. C.

The action of free sulfur on plants. G. BOSINELLI. *Staz. sper. agr. ital.* 48, 175-84(1915). — Expts. were conducted to demonstrate whether S produces a beneficial action on plant growth and whether plants grown in plots treated with S contain a larger amount of protein than plants without S. These expts. were carried on in pots and in the field with wheat, buckwheat and legume. Each series consisted of four pots, one the control and the other three containing different amounts of S. Part of the crop was harvested in the spring and part in the fall. These were weighed and analyzed. In every case the plots treated with S gave a greater yield than the control. The % of protein on the dry basis was sometimes higher in the control and sometimes lower. Field expts. were carried on in plots 2 m. square, 10 g. S being added per sq. m. The results in the field likewise showed an increase in yield due to S in 5 of the 6 plots. Expts. to test the ammonizing effect of S on dried blood showed that any such effect was practically nil after 40 days.
J. A. LECHE.

The conversion of cotton sticks into charcoal for the destruction of the pink bollworm. A. T. MCKILLOP. *Agr. J. Egypt* 3, 127-9(1914); *Expt. Sta. Rec.* 32, 449-50. — By the baladi method (described) the bollworm may be destroyed and from 9 to 55% of the original weight of the stalks be retained as charcoal. A retort which will convert small lots of cotton stalks into charcoal in a few hrs. has been patented; it is capable of making from $\frac{1}{4}$ to $\frac{1}{2}$ a ton per day. Attention is called to the fact that the calorific value of the charcoal is 7,420, as compared with that of 2,744 for cotton wood.

Determination of phosphoric acid in calcium phosphate (KOLTHOFF) 7. Potash from Queensland "prickly pear" 18.

U. S., 1,151,633, Aug. 31. F. S. WASHBURN. A fertilizer containing $\text{NH}_4\text{H}_2\text{PO}_4$ in the form of a dry, porous granular mass, is made by heating a soln. of $\text{NH}_4\text{H}_2\text{PO}_4$, e. g., obtained by treating crude H_3PO_4 (from phosphate rock and H_2SO_4) with NH_3 , to 112° to evap. part of the H_2O , further evapg. *in vacuo* sufficiently to cause the mass to puff up and assume a granular form, and finally completing the drying in a vacuum drier or any ordinary type of drier to obtain a product somewhat resembling pumice stone in appearance, containing only 3-4% H_2O or less. Cf. C. A. 9, 1978.

Brit., 10,202, Apr. 24, 1914. C. E. DE WOLF and H. E. FRY. After treating grain by electrolysis in a soln. of a fertilizer, HNO_3 , etc., as described in 22,151, 1913 (C. A. 9, 839), the grain, instead of being dried, is sprayed with petroleum or benzoline to form a coating. A wooden tank having Fe electrodes covering the entire ends is used for the electrolytic treatment. Solns. of NaCl, sugar, or Fe or Zn salts may be employed. Cf. C. A. 9, 950.

Ger., 284,162, Jan. 30, 1913. BAMBACH & Co. Utilizing the waste liquors of the potash industry, for working up H_2O -insol. K silicates such as phonolite, feldspar, mica, leucite, basalt, trachyte, syenite, etc. In the end lyes of the potash industry, small amts. of KCl, NaCl, and MgSO_4 are present, and in addition about 35% of MgCl_2 for which no application has been found heretofore. Expts. have now shown that MgCl_2 , alone or in admixt. with Ca compds. (CaO , CaCO_3 , brown coal ash, etc.), break up the K silicates, in the heat, converting them into a form available for the soil. A suitable amt. of silicate rock in powder form is charged into a heated revoluble tube furnace, into which the end lyes specified above are allowed to flow. A uniformly intimate mixt. of lye and powdered silicate is obtained. Upon ignition of this mixt. the MgCl_2 splits off HCl. The resulting products, such as HCl, MgO, $\text{MgO} \cdot \text{MgCl}_2$,

are highly effective in disintegrating the silicate. The reaction product contains K in available form, and, after grinding, finds direct application as a fertilizer. If the ground silicate and end lyes are ignited with the addition of Ca compds., such as CaO, CaCO_3 , $\text{Ca(NO}_3)_2$, etc., the principal products are CaCl_2 and CaO.CaCl_2 , which have a still greater disintegrating action than MgCl_2 alone. The gases resulting from the process (HCl , Cl , CO_2 , or NO compds.) are washed in the end lyes or the potash end lye mixt. and find application in the next charge.

Ital., 134,069, Aug. 7, 1913. *SOC. DE PRODUITS AGRICOLES MOUILLANTS A L'ADHESOL.* In a process of modifying anti-cryptogamic and insecticidal preparations, liquid or boiled, and acid, neutral or alk., bile is used as an agglutinant, in the proportion of 500-1000 g. per hectoliter of Bordeaux mixt.

Ital., 138,556, Jan. 27, 1914. *DETIPOS POWER CO., LTD. and J. H. LIDHOLM.* In a process of mfg. fertilizer from N carbides, the furnace is in the form of a bell having a movable bottom for the purpose of permitting the renewal of the charge without stopping to cool down the furnace. Cf. *C. A.* 9, 2037.

16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

Significance of oryzanin for the nutrition of fermentative organisms. K. KURONO. *J. Coll. Agr. Imp. Univ. Tokyo* 5, 305-24(1915); *J. Soc. Chem. Ind.* 34, 810.—Oryzanin is a constituent of the outer portions of unpolished rice and possesses remedial properties with respect to beri-beri. According to Suzuki it is an indispensable constituent of feeding stuffs generally, without which they lose their nutritive value. K. found that, when added to the extent of 0.01-0.1%, it accelerates the growth and fermentation of yeasts in beer-wort, koji ext., and especially in artificial media, such as Hayduck's and Nägeli's soles., its stimulating action being much greater than that of peptone, asparagine, etc. The accelerating action exerted by "indifferent matters," such as maltculms, on distillery fermentations is attributed by K. to the action of oryzanin.

E. J. C.

U. S., 1,152,154, Aug. 31. M. E. DÖNITZ. A fermented non-alcoholic wine is made by distg. off the alc. from ordinary alc. grape or other fruit wine, adding H_2O to restore the vol. of the residue, pasteurizing, adding pure wine yeast and maturing the wine for 4-12 weeks and finally drawing it off from the pptd. yeast and carbonating.

U. S., 1,152,415, Sept. 7. E. HINTERLACH. Beer low in alcohol. The combined beer and wort is held at a low temp. (preferably about 0°) during its refining, before pasteurizing, to ripen it.

M. I. WILBERT.

Thymol production in this country. ANON. *Oil, Paint and Drug Rep.* 88, No. 6, 19(1915).—General article with statistics. E. W. BOUGHTON.

Chloroform denaturant decision. ANON. *Oil, Paint and Drug Rep.* 88, No. 9, 19(1915).—Treas. Dept. decision (T. D. 2234). Formula 20: To 100 gal. EtOH add 1 gal. crude CHCl_3 (d_{20} not less than 1.4). This formula is approved for continuous use in manuf. of CHCl_3 only. E. W. BOUGHTON.

Formation of essential oil in *Ocimum basilicum* in different intensities of light. V. LUBIMENKO AND M. NOVIKOFF. *Bull. Applied Botany* 7, 697-719, 720-4(1914);

Bull. Agr. Intelligence 6, 684.—In order to investigate the influence of light upon the accumulation of essential oils in plants some shading expts. were carried out on sweet basil (*Ocimum basilicum*). The exptl. field, which has a southern exposure, was divided into 4 equal parts, one of which was left uncovered while the others had horizontal cloth shades stretched above them at a height of one meter from the soil. The texture of the cloth varied with each plot and was such that the threads only represented 10, 25 and 50% of the surface, respectively. The plants, when in full bloom, were extd. by distn. in a current of steam. As the illumination decreased, the water content of the plants gradually increased and the stems grew longer. The greatest amt. of vegetative growth, however, occurred with 10% shading only; when the shading was increased to 50% the development of the plant was seriously affected. The production of essential oils was favored by increasing shade, but as the production per unit area also depends on the total yield of dry matter, the largest amt. of essential oil would be obtained with 10% shading and not with 50% shading. E. J. C.

The transformation of nitrogenous substances during artificial curing of tobacco. L. BERNARDINI. *Boll. tecnico della coltivazione dei tabacchi* 13, 288-99(1914); *Bull. Agr. Intelligence* 6, 426.—B. has investigated the changes that take place in the nitrogenous substances during artificial curing as compared with air curing, for the latter method, even after subsequent fermentation, does not succeed in giving good results in the case of five native tobaccos. Conclusions: (1) The art. curing process does not produce any changes in the protein substance of the leaf. (2) In leaves cured by this process there are none of the sol. nitrogenous substances belonging to the amino acids which occur in air-cured leaves. (3) In the art. curing and air curing processes alike, the basic N contained in the leaves corresponds exactly to that present under the forms of nicotine and NH_3 . The consumption of nitrogenous substance observed during art. curing therefore takes place at the expense of the amino acids which are completely used up, while the protein substance and the nicotine remain unaffected. E. J. C.

Importance of the strophanthin reaction when sulfuric acid acts upon strophanthus seed. ALESSANDRO BALDONI. *Univ. Rome. Arch. farm. sper.* 19, 511-28, 534-64 (1915). A. W. DOX.

Inversion of cane sugar in syrupus (U. S. P. VIII). J. L. MAYER. *Am. Druggist* 63, 283-4(1915).—Syrupus made by the hot process contained no more invert sugar than that made by the cold process, very little inversion taking place in either case. C. O. EWING.

Reactions of Kombe and Gratus strophanthin and the distinguishing of these glucosides. C. REICHARD. *Pharm. Zentralhalle* 56, 159-63, 174-8(1915).—R. compares the color reactions of strophanthin obtained from *Strophanthus kombe* and *S. gratus* when treated with various reagents. C. O. EWING.

Some historical and bibliographical notes on the therapeutics and chemistry of the oxypinenes. J. E. BLOMÉN. *Am. J. Pharm.* 87, 398-406(1915).—A review of the literature together with comments by the author. According to B. it appears that an ozonide of pinene prepared from pure pinene and freshly generated ozone would be an ideal therapeutic agent. When such a compd. comes in contact with a moist animal tissue H_2O_2 is gradually and slowly developed, and the intermediary oxypinenes (the aldehydes and ketones) are generally conceded to have greater therapeutic value than the too active turpentine itself. Cf. C. A. 9, 1366, 1769. W. G. GAESSLER.

Wine of beef and iron. GEORGE M. BERINGER. *Am. J. Pharm.* 87, 406-10 (1915).—B. criticises the formula for wine of beef and iron in the N. F., Third Ed., and submits the following improved formula: Dissolve ext. of beef (30 g.) in hot water

(60 cc.), add sirup (100 cc.) and then the compound spirit of orange (1 cc.) and alc. (50 cc.) previously mixed. Dissolve the iron and NH_4 citrate (10 g.) in 750 cc. sherry wine, and add this soln. to the other mixt.; then add sufficient NH_4OH (10%) to make the soln. neutral or only very faintly alk. to litmus paper and then sufficient sherry wine to make 1000 cc. If acid, now add, drop by drop, NH_4OH until neutral or very faintly alk. reaction is obtained. Set aside for 2 days and then filter. An 8-oz. bottle of wine of beef and iron made for the N. F. Revision by the above formula, June 25, 1912, has been kept under observation since that date. For a time it was kept in a cellar, more recently in the lab., subjected to the varying changes of temp. and more or less exposed to light, but to date (after nearly 3 yrs.) it is still clear, free from pptn., and is entirely satisfactory.

W. G. GAESSLER.

Phenoval, a new sedative and hypnotic. SALOMON. Berlin. *Berl. klin. Wochschr.* 51, 935(1914).—Phenoval, $(\text{CH}_3)_2\text{CH}.\text{CHBr}.\text{CONH}.\text{C}_6\text{H}_4.\text{OC}_2\text{H}_5$, is recommended as an excellent sedative and hypnotic when given in warm H_2O in 0.5–1 g. doses. It stops pain and produces a light sleep for 4–10 hrs.

JULIAN H. LEWIS.

Calmonal, a new sedative. v. FEILITSCH. Berlin. *Berl. klin. Wochschr.* 51, 1864–5(1914).—Calmonal has the chem. formula, $\text{CaBr}.\text{CO}(\text{NH}_2)\text{OC}_2\text{H}_5 + 2\text{H}_2\text{O}$. The Br content is 27%. It is a white cryst. substance, easily sol. in H_2O and alc. Its m. p. is 107–107.5°. It is recommended as a good sedative when given in doses of 0.5–1 g.

JULIAN H. LEWIS.

Medicinal chemical compounds protected by trade marks, and the so-called "equivalent" products. DOMENICO MAROTTA. Rome. *Ann. chim. applicata* 3, 325–39(1915).—Many medicinal substances having trade-names are indistinguishable from the equiv. chem compds. Very often, however, foreign substances, such as starch and sugar, are present in the patented pharmaceutical preps. to disguise their compn. By extended tests M. established the identity of "aspirin" with *o*-acetoxybenzoic acid, "duotal" with *o*-methoxyphenyl carbonate, "veronal" with diethylbarbituric acid, "antipyrin" with 1-phenyl-2,3-dimethyl-5-isopyrazolone, "pyramidone" with dimethylaminodimethylphenylpyrazolone, "dermatol" with basic Bi gallate, "diuretin" with Na theobromine and salicylate, "urotropine" with hexamethylenetetramine. The methods of prep. these compds., and the tests used by M. are given.

S. LEVY.

Chemical constituents of Korean ginseng. H. KONDO AND G. TANAKA. *J. Pharm. Soc. Japan*, No. 401, 779(1915).—Korean ginseng was extd. with H_2O , Et_2O and MeOH. The aq. ext. yielded mucilage extensively, which was oxidized by HNO_3 to pyromucic acid. The H_2O -sol. mineral matter obtained by ignition consisted of Fe, Al, Mn, K, P_2O_5 and SiO_2 . The ethereal extract was a yellowish brown oil. It was fractionated with steam into 2 portions. The 1st portion was a light yellow oil. Concd. H_2SO_4 colors this product yellowish brown, which upon the application of gentle heat for a few moments, turns to violet-red. When dissolved in Ac_2O , a magnificent violet color is formed upon the addition of a drop of concd. H_2SO_4 . This product also yielded the terpene, panacene. The 2nd fraction was yellowish brown, and possessed a sirupy consistency. It responded to the phytosterol reaction of Hesse. After sapon. by alc. KOH, a form of phytosterol was obtained, m. 133°, $[\alpha]_D^{20} - 29.1^\circ$. Further sepn. yielded an amorphous acid m. 150–6°. The MeOH ext. contained appreciable amounts of cane sugar with traces of a nitrogenous substance and a glucoside resembling saponin. The ext. was dissolved in H_2O after eliminating MeOH, and pptd. by $\text{Pb}(\text{OAc})_2$. The ppt. was suspended in H_2O and H_2S introduced at 40°. The filtrate was exactly neutralized with NaOH and allowed to stand after the addition of $\text{Ba}(\text{OH})_2$ soln. The Ba compd. of the saponin-like substance was collected and suspended in H_2O and freed from Ba by means of CO_2 . The soln. was evapd. *in vacuo* and the residue dissolved in MeOH and pptd. with Et_2O . The purified powder, m. 220°, does not

reduce Fehling soln. Conc'd. H_2SO_4 produced a crimson color; 1% H_2SO_4 , hydrolyzed it to prosapogenin containing sugar, and after 60 hours' digestion sapogenin free from sugar was obtained. The H_2O -sol. cleavage products responded to the pentose reaction and *d*-glucose was present as proved by the osazone reaction. SIMON MENDELSSOHN.

The preparation of alkaloid hydrochlorides from opium. (Hydrochloras toponali.)

C. A. HUBER AND P. VAN DER WIELEN. Amsterdam. *Pharm. Weekblad* 52, 860 (1915).—The making of an opium prepn. corresponding to "Pantopon" is described. The method of prepn. consists in mixing 50 g. of powdered opium with 300 cc. H_2O and adding small amts. of dil. HCl (about 15 cc.) until a slight color is obtained with Congo red paper. The soln. is allowed to stand 2 hrs. with stirring, adding a few drops of HCl to make weakly acid, decanted, the mass pressed out, and washed 3 times with 100 cc. water. The manipulation must be completed within 3 hrs. The ext. is filtered at once, the filtrates are combined, treated with a soln. of 35 cc. NH_4OH in 65 cc. H_2O , and allowed to stand 12 hrs. The alkaloids are collected, washed on the filter with water until the wash water is colorless, after which the filtrate and wash water are extd. 3 times with 1 liter Et_2O , rendered alk. with NaOH, and again extd. 3 times with Et_2O as before. Each time after the shaking, 10 to 15 cc. alc. is added to hasten the sepn. of the Et_2O . The ethereal solns. are combined and shaken with several 5 cc. portions of H_2O . The Et_2O is distd. off, the residue added to the alkaloids sepd. by the NH_4OH and the whole dissolved by warming on the water bath with 500–600 cc. H_2O , to which HCl is added dropwise until the soln. is weakly acid to litmus paper. The aq. soln. is treated with 10 g. fullers earth previously washed with HCl and H_2O , cooled, filtered, evapd. to dryness *in vacuo*, and pulverized. P. v. D. M.

Chemical patents. S. C. MASTICK. *J. Ind. Eng. Chem.* 7, 789–97(1915).—Lecture to students on patent law and procedure as related to chem. patents. I. M.

Tinctures and extracts in therapeutics. LUIGI PESCIATELLI. *Boll. chim. farm.* 53, 335–43(1914).—P. discusses the history and methods of prep. of fluid, semi-fluid and dry exts. and tinctures. There is appended a tabulated list of approx. 100 drugs, for each of which the therapeutic action and the av. wt. of the principal active substances present in 1 g. of the drug are given, as well as the amts. of fluid, semifluid and dry exts. and tinctures, resp., which correspond to 1 g. of the drug. H. S. PAINE.

The composition of commercial samples of oil of santal and balsam of copaiba. WILHELM BECKERS. *Südd. Apoth.-Ztg.* 55, 12–3(1915).—The copaiba of 2 samples of capsules of balsam of copaiba was found to be pure, and the copaiba of 6 samples was found to be adulterated with gurjun balsam. The acid no. varied from 70.4 to 134.4, and the sapon. no. from 42 to 168. The oil in 5 samples of capsules of oil of santal was found to have an acid no. from 5.61 to 8.41 and santalol content from 70.30 to 92.80%. The detection of gurjun balsam by the Ph. Germ. V method is too complicated and the method outlined by Riedel is preferable. In this method, 4 drops of balsam of copaiba are dissolved in 15 cc. of acetic acid and the soln. treated with 4 drops of HNO_3 having a sp. gr. of 1.4. A rose red color is immediately produced in the presence of gurjun balsam. This color, in the course of time, dependent on the amt. of adulteration present, becomes deeper and gradually becomes violet. M. I. W.

Apomorphine reactions. WILHELM BECKERS. *Südd. Apoth.-Ztg.* 55, 198(1915).—A review of the available reactions for apomorphine. M. I. W.

Rate of evaporation of ether from oils (BASKERVILLE) 11A.

U. S., 1,148,637, Aug. 3. A. THIELE. **Diketopyrrolidine derivatives.** *p*-Methyl-diphenylbenzoyldiketopyrrolidine, cryst. m. 248° is made by heating *p*-toluidine with benzaldehyde in abs. alc., adding Et sodiobenzoylpyrrolacetate dissolved in abs. alc.

and glacial HOAc, heating for 12 hrs. and pptg. with HCl, purifying through the Na salt and cryst. from alc. *1-o-Tolyl-2-phenyl-3-acetyl-4,5-diketopyrrolidine*, rose colored cryst., m. $177-9^{\circ}$, is made by reaction in Et₂O soln. of *o*-toluidine and benzaldehyde on Et acetylpyrroacetate. *1-o-Methoxyphenyl-2-phenyl-3-acetyl-4,5-diketopyrrolidine*, m. $225-7^{\circ}$ (decompn.), is made by reaction in ether soln. of anisidine, benzaldehyde and Et acetylpyrroacetate; *1-Phenyl-2-piperonyl-3-acetyl-4,5-diketopyrrolidine*, m. 197° , by heating together aniline, piperonal and Et acetylpyrroacetate, in C₆H₆. *1-p-Tolyl-2-p-dimethylaminophenyl-3-acetyl-4,5-diketopyrrolidine*, a brown powder, m. 166° (decompn.), is made by reaction in C₆H₆ of Et acetylpyrroacetate, *p*-toluidine and *p*-dimethylaminobenzaldehyde. *1-Quinoly-2-phenyl-3-acetyl-4,5-diketopyrrolidine*, m. 222° (decompn.), is made from 8-aminoquinoline, benzaldehyde and Et acetylpyrroacetate in C₆H₆ soln. *1-[1-Phenyl-2,3-dimethyl-5-pyrasolyl]-2-phenyl-3-acetyl-4,5-diketopyrrolidine*, a light brown powder, with a bitter taste, decomp. on heating, is made from phenyldimethylaminopyrazolone, benzaldehyde and Et acetyl pyrroacetate, by heating in C₆H₆ at $100-10^{\circ}$ for 5-6 hrs. *1-Phenyl-2-furfuryl-3-acetyl-4,5-diketopyrrolidine*, yellow-green cryst., sol. in alc. and ether and m. 190° (decompn.), is made by heating furfural, aniline and Et acetylpyrroacetate in C₆H₆ on a H₂O-bath for 2 hrs. *1-o-Methoxyphenyl-2-phenyl-3-benzoyl-4,5-diketopyrrolidine*, cryst. m. $215-7^{\circ}$ (decompn.), is made by reaction of *o*-anisidine, benzaldehyde and Et benzoylpyrroacetate in C₆H₆ for 24 hrs. All these compds. are insol. in H₂O, difficultly sol. in ether and C₆H₆, sol. in alkalies and stable when heated with dil. acids or alkalies. They are proposed for use as medicines.

U. S., 1,149,712, Aug. 10. L. G. BLECKWENN. Basic aluminium salts of formaldehyde-sulfurous acid are made by combining 1 mol. proportion hydrated Al₂O₃, CH₂O and SO₂.

U. S., 1,150,251, Aug. 17. A. B. DAVIS. Dimethylaminomethylethylamylcarbinol is made by reacting on chloromethyl ω -bromopropyl ketone with EtMgBr, and condensing the tertiary alc. produced with Me₂NH. It is a colorless liquid, b₁₅ 96° . It is a local anesthetic.

U. S., 1,150,252, Aug. 17. A. B. DAVIS. Dimethylaminomethylethylisoamylcarbinol, is made by reacting upon epichlorhydrin with iso-BuMgBr oxidizing the chloromethylisoamylcarbinol formed with K₂Cr₂O₇ to a ketone, reacting on the ketone with EtMgBr to form chloromethylethylisoamylcarbinol and condensing the latter with Me₂NH. It b₃₀ $132-8^{\circ}$ and is a local anesthetic.

U. S., 1,150,253, Aug. 17. A. B. DAVIS. Dimethylaminomethylethylisoamylcarbiny benzoate is made by esterifying dimethylaminomethylethylisoamylcarbinol with BzCl in hot C₆H₆ soln. The ester is a local anesthetic, sol. in H₂O. It forms white prismatic crystals.

U. S., 1,151,113, Aug. 24. H. W. MATHESON. Acetaldo is made by reaction of alc. KOH soln. on acetaldehyde below 10° . The free alkali is then neutralized and the acetaldo is recovered by distn. *in vacuo*.

U. S., 1,151,255, Aug. 24. G. E. FERGUSON. Corrosive action of carbon tetrachloride or other halogenated hydrocarbon due to absorption of O, is prevented by the addition of BzH, toluene, BzCl or PhCHCl₂.

U. S., 1,151,536, Aug. 24. E. ABDERHALDEN. A serum for treating cancer is obtained by injecting cancerous tissue into a horse, bleeding after 2-5 days, sepg. the serum and injecting it into another animal, and then obtaining serum from the latter. By repeated transfer from one animal to another the proteolytic and curative action of the serum is greatly increased. Similar transfers may be made with advantage in prepg. some other remedial sera.

U. S., 1,151,885, Aug. 31. W. KROPP. A condensation product of acetylpyruvic acid and phenylaminopyrazolone is made by reaction of 1-phenyl-2,3-dimethyl-4-amino-5-pyrazolone on the "Na salt of acetone-oxalic ester." The product is cryst., yellowish, difficultly sol. in H_2O and organic solvents, m. $215-20^\circ$, easily sol. in alkalis and forms salts having antipyretic and antineuralgic properties. Similar products are obtained from benzoylpyruvic acid (cryst. m. 195° ; quinine salt m. 210°) or from acetylpyruvic acid and 1-m-tolyl-2,3-dimethyl-4-amino-5-pyrazolone (m. 175°).

U. S., 1,151,928, Aug. 31. P. DUDEN and G. PETERS. Acetaldehyde is made by oxidizing C_2H_2 in a soln. containing 6% H_2SO_4 , 3% $HgSO_4$ or other Hg salt, and a small amt. of $Fe_2(SO_4)_3$. The latter retards the sepn. of Hg from the soln.

U. S., 1,151,929, Aug. 31. P. DUDEN and G. PETERS. Acetaldehyde is made by oxidizing C_2H_2 in a dil. H_2SO_4 soln. of $HgSO_4$ or other Hg salt, using a small amt. of CrO_3 in the soln. to prevent sepn. of Hg.

U. S., 1,152,098, Aug. 31. F. KAUFLEER. Acetic anhydride is made by heating ethylidene diacetate to $250-300^\circ$ preferably with a catalyzer of Cu chips, pumice, $KHSO_4$, H_2SO_4 or $HgSO_4$.

U. S., 1,153,121, Sept. 7. J. LAGUTT. *o*-Sulfamidobenzoyl-*p*-phenetidine, white, lustrous, tasteless cryst., m. $171-2^\circ$, sol. in H_2O and alc. is made by heating *o*-benzoic sulfimide with *p*-phenetidine, in mol. proportions, to 120° for 5-6 hrs., treating with H_2O and soda and crystg. from toluene or alc. It resembles pyrimidine in physiological action.

Aust., 9,181, Oct. 27, 1913. F. WISCHO. In a powder or paste for removing tartar from teeth, employing the neutral alkali- or NH_4 -salts of acids whose Ca salts are sol. in H_2O . This product is combined with a scouring agent which does not contain Ca comps. sol. in the aforesaid salt solns., and as a binder only a suitable neutral or neutralized ingredient is employed.

Brit., 10,176, Oct. 3, 1913. KALLE & Co. Therapeutic products are obtained from non-acidproof bacteria, such as those of anthrax, typhus, etc., by extg. the bacteria, preferably dried and finely ground, first with alc. and then with ether or other fat-extg. solvent; the alc. ext., ether ext., and residue may all be used for inoculating purposes.

Brit., 9,745, Apr. 20, 1914. B. L. MALTBIE. A creosote preparation for use in tuberculosis, bronchitis, and kindred diseases, without producing nausea, consists of a chem. combination of $Ca(OH)_2$ and beechwood creosote. The creosote and CaO are mixed together, and sufficient H_2O added to slake the oxide. The product is then quickly dried.

Brit., 10,198, Apr. 24, 1914. W. A. WHATMOUGH. The adhesive structure of molded menthol and its power of adhesion to a holder are increased by adding to the liquefied menthol a natural wax, fat, or oil, or a fatty acid or its alc. or ester. Examples given are stearin, synthetic glyceryl stearate, and octadecyl alc. The molded product is attached to a holder in the ordinary manner.

Brit., 10,377, Apr. 27, 1914. FARBW. v. M. L. & B. Acetic acid is prepared by oxidizing aldehyde with air or O in the presence of a catalyst and under pressure.

Brit., 10,946, May 4, 1914. RICHTER GEDÉON VEGYESZETI GYÁR. Magnesium *o*-acetoxybenzoate is obtained by stirring *o*-acetoxybenzoic acid with MgO , $Mg(OH)_2$, or $MgCO_3$, and a little H_2O , extg. the product with $MeOH$ or $EtOH$, filtering and pptg. by means of ether.

Ger., 283,825, Nov. 2, 1913. BAYER & Co. Addition to 282,455 (C. A. 9, 2426). Production of hydroxyquinoline containing iodine and bismuth, the nucleus homologs

and their substitution products. Instead of employing BiOI, in connection with hydroxyquinoline, HI is brought into reaction with Bi compds. of *p*-hydroxyquinoline, or Bi compds. are allowed to act on the hydriodides of hydroxyquinolines.

Ital., 135,560, Aug. 25, 1913. SOCIETÀ "BOGATIR." In a process of mfg. pinacone from acetone, the latter is treated in the presence of metallic condensing agents, such as the salts of Hg, with an amalgam of Na, Al, Cd, etc., whereupon the pinacone alcoholate resulting is decomposed by H_2O .

Ital., 141,268, May 6, 1914. A. PETRILLO. In a process of mfg. acetone, a low grade sugar is employed as the initial material, wherein alc. and acetic acid fermentation are induced. The mass is then neutralized with $CaCO_3$, and the resulting Ca acetate is subjected to distn.

Ital., 141,773, May 14, 1914. GES. FÜR ELEKTRO-OSMOSE. Mfg. chemically pure silicic acid by subjecting solns. of alk. silicates to the action of the elec. current in the anode compartment of an element with a diaphragm.

18. ACIDS, ALKALIES, SALTS AND SUNDRIES.

T. LYNTON BRIGGS.

The current status of the borax industry. S. H. DOLBEAR. *Mel. Chem. Eng.* 13, 564(1915).—A general discussion. E. J. C.

The world's potash. ANON. *Chem. News* 112, 81(1915).—A brief review of a pamphlet issued by the Imperial Inst. of Great Britain. Both the old and new sources of K are described so far as details are available. The increased production of K in the United Kingdom from kelp and other vegetable sources is now under serious consideration. F. W. SMITHER.

Potash from Queensland "prickly pear." ANON. *Chem. News* 112, 81(1915).—A brief review of the measures being conducted on the property of the Cactus Estates Co., at Dulacca, for the destruction of the prickly pear pest by the use of $AsCl_3$. The ash from 5 acres yielded a half ton of 80% K_2CO_3 per acre, i. e., prickly pear ash yields 15% K_2O . As high as 7 tons of ash per acre have been recovered, including wood ash. A vacuum machine has been designed to pick up the ash. It is believed that the K_2O yield would pay for clearing land which could not be profitably touched otherwise. F. W. SMITHER.

Sawmill waste as a source of potash. C. T. GIMINGHAM. *J. Board Agr.* 22, 146-8(1915).—Analyses of ash from wood-scrap, sawdust and shavings show that dust from boiler-flues and chimneys contains as high as 10% K_2O , while ordinary coarse ash contains 5 to 7%. It is claimed that timber merchants would profit by erecting plants to burn their scrap. E. J. C.

Iodine from Russia. ANON. *Journale Zaria; Pharmazevtizeski Journal; J. pharm. chim.* 11, 313-4(1915).—The alga *Fillafora*, growing abundantly in the Black Sea, yields 11% of ash containing up to 3.8% I (Zernoff). A specimen from the Sebastopol Museum showed 11% ash containing 2.3% I (Pissarevsky). The growth is incinerated, the iodide extd. with EtOH, not with H_2O , and the I set free and collected by a secret process (Pissarevsky and Averki). Ekaterinoslav is the center of prospective manufacture. S. WALDBOTT.

Preparation and uses of animal charcoal. W. WIECHOWSKI. *Oesterr. Chem. Ztg.* 18, 74-5(1915).—A general discussion. ARTHUR LEDERER.

Coloring horn (BEUTEL) 25.

U. S., 1,150,899, Aug. 24. E. H. STRICKLER. **Monosodium phosphate** is made by treating Na_3PO_4 with H_2SO_4 , concg. the soln. until the Na_2SO_4 seps., and drawing off the liquid and crystg. KH_2PO_4 may be similarly made and HCl , HNO_3 or HOAc may be substituted for H_2SO_4 .

U. S., 1,150,900, Aug. 24. E. H. STRICKLER. **Monosodium phosphate** is made by first forming Na_3PO_4 by furnacing a mixt. of rock phosphate with NaHSO_4 and carbonaceous fuel, treating the Na_3PO_4 thus obtained with H_2SO_4 to form H_2PO_4 and Na_2SO_4 , sepg. the H_2PO_4 and treating it with sufficient Na_3PO_4 to form NaH_2PO_4 , and converting the Na_2SO_4 into NaHSO_4 for further use in the process. Other acids may be substituted for H_2SO_4 .

U. S., 1,151,074, Aug. 24. F. S. WASHBURN. **Apparatus for making ammonium phosphate from phosphate rock.** Phosphate rock and H_2SO_4 are mixed in the tank 1, the liquor produced is passed through the filter 2, heated in the tank 6 and then passed successively through the ammoniating towers 8 and 9. Steam from the second ammoniating tower is led to the heating tank and fresh acid is supplied as necessary to the tank 25. The liquor is concd. in evaporators 15, 16,

17 and collected in tanks 19, 20. 21 is a surface condenser.

U. S., 1,151,103, Aug. 24. H. HOWARD. **Making sulfuric acid.** A mixt. of H_2SO_4 and NaNO_3 in the mol. proportions 1:2 is mixed, heated and stirred in the vessel 1, and then heated in the furnace 6. The evolved N oxides are led through the outlet 12 and mixed with sulfurous gases in the flue 13 leading to the Glover tower and the solid Na_2SO_4 remaining is continuously drawn off through the outlet 12 and collected at 14.

U. S., 1,151,294, Aug. 24. G. SCHLIEBS. **Apparatus and process for making sulfuric acid.** The acid vapors and gases are led through a series of towers a to a separator b, then through another tower a to another separator b, and so on as shown in the fig. Fans d in the conduits c force a portion of excess uncondensed vapors and gases back from each of the separators to the preceding towers so that each series of towers and separators is forced to condense its proper portion of vapors and gases.

U. S., 1,151,498, Aug. 24. F. A. RODY and H. M. BURKEY. **Obtaining alkalis and alumina from feldspar, leucite and similar minerals.** The alkali-bearing silicate

is heated to a sintering temp. with additional alkali, *e. g.*, Na_2CO_3 , and CaO , in sufficient amt. to form a H_2O -sol. alkali aluminate and mono- Ca silicate.

U. S., 1,151,533, Aug. '24. F. A. RODY. **Obtaining alkalies and alumina from feldspar, leucite and similar minerals.** The mineral is sintered with sufficient CaO to produce Ca orthosilicate and a H_2O -sol. alkali metal aluminate and the sintered mass after crushing is treated with boiling H_2O . The CaO is formed in the mass by adding CaCl_2 soln., and decomposing with steam (recovering HCl formed).

U. S., 1,151,537, Aug. 24. F. W. DEJAHN. **Producing ammonia.** A mixt. of H and N is passed over a catalyst formed by heating Na or K on pumice in NH_3 to 300° at 550 – 600° under a pressure of 34 – 95 atm.

U. S., 1,151,553, Aug. 31. R. ADLER. **Animal charcoal for use in purifying solutions** is made by washing, boiling, drying and then carbonizing fish.

U. S., 1,151,690, Aug. 31. E. F. KELLEY. **A friction fabric for brake-linings, etc.,** is made of woven asbestos impregnated with a mixt. of alum, MgSO_4 and a decoction of ground bone.

U. S., 1,151,849, Aug. 31. J. W. AYLSWORTH and E. L. AITEN. **Sound-records** are made with a body layer of wood fiber or other filler and a binder of phenolic condensation product and a surface layer of fusible phenol resin mixed with chloronaphthalene or other material which will increase its plasticity.

U. S., 1,152,044, Aug. 31. J. F. PLACE. **Heat-interchange system for liquifying air.**

U. S., 1,152,066, Aug. 31. A. WOLFF. **A solution of hydrogen peroxide with a high content of O_3 and O_2** is produced by adding about 0.7 – 0.8% NaCl to a soln. of H_2O_2 of 3% or higher strength, satg. the soln. at 0 – 2° with O_3 and then spraying it through a chamber containing compressed O_2 .

U. S., 1,152,119 and 1,152,120, Aug. 31. J. F. PLACE. **Methods of heat-interchange for liquefying air and separating its constituents.**

U. S., 1,152,193, Aug. 31. M. MARSA. **Artificial cork** is formed of granular cork mixed with a binder of defibrinated blood, turpentine and glycerol.

U. S., 1,152,196, Aug. 31. A. MESSERSCHMITT. **Making hydrogen.** A reaction mass, 32, composed of spongy Fe or Fe ore is heated from the combustion chambers 3 and 12 and alternate currents of steam and reducing gas are passed through the reaction mass. After steaming, heating and reduction are effected by passing a mixt. of combustible gas and air through one of the combustion chambers, then through the reaction mass and then through the second combustion chamber during the first portion of this step. Then the air is cut off, and the flow of combustible gas continued for some time, the residual gas passing through the reaction mass being burned in the second combustion chamber by air supplied directly to it. 31 is a hood for waste gases and 27 is the outlet for H .

U. S., 1,152,244, Aug. 31. G. N. VIS. **Ammonium sulfate** is made by "emulsifying" gypsum with H_2O , adding it, together with $(\text{NH}_4)_2\text{CO}_3$ to a conct. soln. (at least 30%) of $(\text{NH}_4)_2\text{SO}_4$ and stirring the mixt.

U. S., 1,152,197, Aug. 31. **A. MESSERSCHMITT. Making hydrogen.** A reaction mass of spongy Fe which is alternately treated with steam and reducing gas, is heated after steaming by burning gas in annular zones around short layers (A, B, C and D) of the material. The mixt. of gas and air is supplied through the pipes 16, 17, 18, 19, 20, 21, 22, 23, combustion products being drawn off through the material and the flow of reducing gas being continued after cutting off the supply of air. Waste gases are vented at 26 and H at 28.

U. S., 1,152,245, Aug. 31. **G. N. VIS. Ammonium sulfate.** See Brit., 2,002 (C. A. 8, 2462).

U. S., 1,152,499, Sept. 7. **H. FRASCH. Mining sulfur by the fusion process.** H_2O is withdrawn from a H_2O -flooded subterranean deposit of S at a temp. below the m. p. of S and at the same time a portion of S in the deposit is fused by introduction of hot H_2O and the fused S is withdrawn from the deposit.

U. S., 1,152,625, Sept. 7. **B. B. GOLDSMITH. A composition for uses similar to those of celluloid** is made by treating soy bean, castor, or similar vegetable oil with 50% of dil. HNO_3 at about 100° to oxidize it without nitration and mixing the product with nitrocellulose and solvents.

U. S., 1,152,777, Sept. 7. **F. J. WOOD. Evaporating brine to recover salt.** The brine is heated in 2 or more stages by surface contact with heated air under pressure.

U. S., 1,152,930, Sept. 7. **C. BOSCH, A. MITTASCH, H. WOLF and G. STERN. Making ammonia synthetically** by passing H and N over Fe, and Al_2O_3 or other carrier, under 100 atm. pressure or more at 450° .

U. S., 1,152,949, Sept. 7. **J. H. HIRT. Sodium hydroxide** is made by allowing molten Na_2S to flow into H_2O and adding $Ca(OH)_2$ to the hot dil. soln., in small portions.

U. S., 1,152,964, Sept. 7. **W. NIELSEN. Dental models** are made, using a negative impression of plaster of Paris 4 and potato flour 1 part, molding the positive of plaster of Paris, and detaching the positive and negative from each other by immersion in hot H_2O .

U. S., 1,153,054, Sept. 7. **F. C. FRARY. Finely divided pure phosphorus sesquisulfide** is made by agitating S and P together at the b. p. in an inert solvent such as α -chloronaphthalene which has a b. p. above 180° and sepg. the product by cooling and agitation. The process is carried out in an atm. of CO_2 .

Aust., 9,445, Nov. 5, 1913. **FORBESER KIESELGUHR- UND TONWERKE. Mfg. insulating, covering, and finishing plates** by intimately mixing with H_2O , to a thin slurry, Kieselguhr 50, asbestos fiber 30, best kaolin 10 and gypsum 10%, pouring this mass into molds, and drying at 80° .

Brit., 9,087, Apr. 9, 1914. **GE. SIEMENS & Co. Addition to 8,015, 1914 (C. A. 9, 2575). Double fluorides of rare earths** and the metal of one of the precipitants mentioned in the parent specification, particularly fluorspar, are produced by stopping the reaction when an intermediate compd. (the double fluoride) has formed and before it is decomposed. The reaction is stopped by filtering off the ppt. To det. the

point at which this should be done, samples of the ppt. may be analyzed from time to time. A clarification, which occurs in the liquid when the double salt has been formed and is followed by a cloudiness when the double salt begins to decompose, is also an indication of the time to stop the reaction. In an example, raw oxides of rare earths in the form of a residue in the extrn. of Th are dissolved in a small excess of HCl or HNO₃, fluorspar is added, and the mixt. is boiled for 1/2 hr.

Brit., 9,271, Apr. 14, 1914. **BADISCHE.** Removing carbon monoxide from gases containing it by treatment with solns. of ammoniacal cuprous oxide containing little or no halogen. In this prepn. of such solns., weak acids, such as CO₂ or organic acids, may be employed, or little or no acid may be used in such prepn. According to examples, solns. are prepared by mixing Cu₂O, (NH₄)₂CO₃, NH₄OH, and H₂O, or by dissolving Cu(OH)₂ in NH₄OH and shaking with finely divided Cu; HOAc or tartaric acid, or their NH₄ or Cu salts, may be added. The removal of CO may be effected under pressure; the process is particularly applicable to the removal of small quantities of CO from H. Cf. C. A. 9, 2299, 2575.

Brit., 9,390, Apr. 15, 1914. **A. HEINEMANN.** Condensation products from phenols, cresols, and formaldehyde or the like are prepd. by passing SO₂ into the mixt. of the parent materials, or a liquid hydroxybenzyl alc. prepd. therefrom, and allowing the action to proceed without the application of external heat. The process is carried out in the absence of a solvent.

Brit., 9,534, Apr. 17, 1914. **SIEMENS & Co.** Addition to 8,015, 1914 (C. A. 9, 2575). Double fluorides of rare earths and the metal of one of the precipitants mentioned in the parent specification, particularly fluorspar, are obtained by conducting the reaction in the presence of an organic acid, such as (HOCO)₂, which may be first added to the rare-earth soln. The ppt. is of granular nature and may be converted into rare-earth fluorides without losing its form, by heating in the mother liquor.

Brit., 9,775, Apr. 20, 1914. **M. P. P. GLOESS, L. P. J. DARRASSE and E. R. DARRASSE.** The extraction of iodine, mineral salts, mucilage and cellulose from seaweed. See U. S., 1,103,283 (C. A. 8, 3119).

Brit., 9,918, Apr. 22, 1914. **C. BUTTERS.** For discharging the cake from a leaf filter for slimes, the cake is satd. with liquid from the inside, arrangements being made to prevent the pressure of the liquid within the filter from being greater than that outside.

Brit., 9,920, Apr. 22, 1914. **C. BUTTERS.** For discharging the cake from a leaf filter, the cake is especially dried by prolonging the vacuum, and then flooded with liquid.

Brit., 9,968, Apr. 22, 1914. **P. M. PIERSON.** A composition for cleaning cinematograph films. See Fr., 465,596 (C. A. 8, 3538).

Brit., 9,973, Apr. 22, 1914. **P. M. PIERSON.** A composition for cleaning cinematograph films consists of an oily material, ether, and camphor.

Brit., 9,974, Apr. 22, 1914. **FARBW. v. M. L. & B.** Manuf. of nitrogen oxides and nitrogen. According to the process of 3,662, 1913 (C. A. 8, 2607), NH₃ is burnt in air with the aid of a catalytic agent, the proportions of NH₃ and air being such that only N oxides and N are contained in the resulting product. In the present process, part of the air is replaced by O, the proportion of NH₃ being still such that after combustion no excess of O remains. Elevated pressures may be used in the process.

Brit., 10,126, Apr. 24, 1914. **J. WUNSCH.** Decolorizing charcoal is obtained by heating any C-containing substance such as wood, sawdust, cellulose, starch, sugar, peat, brown coal, coal, animal offal, etc., with ZnCl₂ or a soln. thereof until carbonization is effected. The ZnCl₂ is removed by washing with H₂O, with addition of acid,

if required. Spent, decolorizing charcoal may be revived in the same way; cellulose may be added to the decolorizing charcoal, and is carbonized in the subsequent re-vivification. Ca compds. may be removed by treatment with HCl before revivification.

Brit., 10,175, Apr. 24, 1914. GEB. SIEMENS & Co. Complex fluorides, such as borofluorides, silicofluorides, titanofluorides, are prepared by reacting with HF on a mixt. of a metal oxide or salt such as a carbonate or chloride and an oxide such as H_2BO_3 , H_2TiO_3 or SiO_2 , capable of forming complex F acids. Examples are the production of KBF_4 from potash or KCl or $K_2B_4O_7$ and H_3BO_3 ; K_2TiF_6 from KCl and H_2TiO_3 . When Na salts are prepared, the process is modified if the products are sol., the soln. being concd. and then purified. If Na and K salts are prepared together, they may be sepd. by their differences of solubility.

Brit., 10,304, Apr. 25, 1914. L. W. DAMMAN. Ground rock salt. See Ger.; 276,344 (C. A. 9, 362).

Brit., 10,379, Apr. 27, 1914. AKT.-GES. FÜR ANILIN-FABRIKATION. In the process of 19,688, 1912 (C. A. 8, 2039), instead of *p*-dichlorobenzene, other chlorinated benzenes or Cl derivs. of homologs of benzene are employed for protecting furs, etc., from moths, etc., and for killing these and other pests, such as fleas, wood-lice, ants, bugs, phylloxera, and weevils.

Brit., 10,420, Apr. 27, 1914. E. A. ASHCROFT. The fixation of nitrogen is effected by treating a mixt. of a metal, such as Na, with C and, with or without a catalyst, with N at a temp. not greater than 700° and a pressure of 50 atms. or more. Na subcyanide, Na_2CN , is produced by heating Na and C in N under these conditions. It is a powerful reducing agent, and may be used instead of Na to obtain NaCN from $Na_4Fe(CN)_6$. It may be converted into Na_2NCN by heating with NH_3 , or into a mixt. of NaCN and NaOH by treatment with H_2O , H being evolved in both cases. If a catalyst, such as Fe, be mixed with the Na and C or with the Na_2CN , and the whole heated with N under the stated conditions, Na_2NCN is obtained, which, after removing the catalyst, may be heated with C to obtain NaCN, or may be treated with steam or H_2O under pressure to obtain NH_3 and alkali carbonate. H or coal-gas may be mixed with the N used in the above reactions, and C may be supplied to the charge by adding naphthalene, benzene, acetylene, paraffin, or the like. The Na may be in the metallic form prepd., *e. g.*, as described in 1,001 and 1,003, 1912 (C. A. 7, 2163) or dissolved in NaOH as obtained by the process described in 228, 1910 (C. A. 5, 3013) and 1,002, 1912 (C. A. 7, 2163), in which case the melt may be circulated between the pressure vessel and the secondary cell of the electrolytic app.; or an alloy may be used, such as a Pb-Na alloy; or the mass obtained by strongly heating charcoal impregnated with fused or dissolved alkali hydroxide or carbonate. The Fe employed as catalyst may be that obtained in prepg. NaCN by reacting with Na on fused $Na_4Fe(CN)_6$. Other metals, especially those of the Fe group, or any metallic compd. having catalytic properties, may be used. The app. employed in the N-fixing reactions may be a polished Fe or steel crucible set within an autoclave capable of standing high pressure; or the gases may be circulated by a pump connected with a pipe dipping into the reaction mixt., which is then maintained in fusion; or charcoal may be packed in an upright column or pressure vessel, the melted Na being forced through it by means of a pump or squeezing device, and the Na traveling downwards with the compressed N; or a mechanical device resembling a ball-mill may be employed. It is stated that, in the production of Na_2NCN by the help of a catalyst as above described, if the Na is placed in a sep. vessel in contact with the N and H which is also in contact with the mixt. of C and catalyst, practically no reaction occurs unless the conditions are such as to allow of the formation of NH_3 by catalytic action, when Na_2NCN is slowly produced, a part of the C being taken up by the gases.

Brit., 10,476, Apr. 28, 1914. I. LITTLEFIELD. A **metal polish** consists of Al silicate, $(\text{HOCO})_2$, paraffin or other oil, and H_2O .

Brit., 10,612, Apr. 29, 1914. G. CALVERT. In the **catalytic synthesis of ammonia**, the catalyst, or heater, or both of these are moved relatively to the gases by an enclosed motor. By this arrangement, moving joints under pressure are avoided, and opportunity is given for the escape of the nascent NH_3 by reason of the continual change in position of the reaction zone.

Brit., 10,797, May 1, 1914. J. L. HALMAN. A **washing composition**, for cleaning clothes, crockery, etc., and for removing paint, enamel, or varnish, 1 or more coats at a time, consists of an aq. soln. of not more than 10% of alkali hydroxide, not more than 2% of alkali carbonate, and about 3% of NH_4Cl and 5% of MeOH or EtOH .

Brit., 10,808, May 1, 1914. H. G. HUGGINS. In the **manuf. of polishing cloths**, the material, such as flanelet, is first treated to remove the dressing therefrom, and the polishing agent is then applied to it. The dressing is removed by passing the material around rollers through an acetic acid bath, the material being then passed over a muslin pad or strainer and pressed between rollers and dried. The acetic acid soln. in the bath is then replaced by a polishing soln. obtained by whipping together oleic acid, pptd. SiO_2 or tripoli, and H_2O , to which rouge or other coloring matter may be added, and the material is again passed through the bath and between rollers, the pressure on the material at this stage being limited to the wt. of the upper roller. The cloth is then hung up to dry.

Brit., 10,977, May 4, 1914. C. CAPSONI. **Equally subdividing loose substances**, such as hair, grain, etc., by scattering the material in the upper part of a closed chamber, in which it falls uniformly, and collecting it in a revolving circular receptacle divided radially into a number of sector-shaped parts of detd. capacities.

Brit., 11,001, May 4, 1914. P. ZÜRN. A **metallic non-corrosive lining for tanks**, etc., made of cement and concrete, is obtained by applying, first a coating of a metal, such as Fe, which is not attacked by the concrete, and, second, a coating of metal, such as Al, Pb, Cu, etc., indifferent to the liquid to be stored. The coatings may be applied by spraying.

Fr., 475,034, July 11, 1914. H. SCHROER. A **compn. for preventing the fouling of window glass**, as by tarnishing by coating with ice, as well as by the adhesion of drops of rain, consisting of fruit juice, such as apple or orange juice, preferably dild. by H_2O .

Ger., 284,042, Sept. 26, 1913. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. **Prepn. of lime for absorption of nitrous gases** at 300–400°, by burning CaCO_3 , in lump or briquet form, with the aid of hot gases at 700–750°. At higher temps. the absorptive power is weakened materially. If the nitrous gases have a temp. of about 800°, the contained heat is sufficient to burn the amt. of CaCO_3 required for the absorption.

Ger., 284,176, May 2, 1914. BADISCHE. **Mfg. hydrogen** by reaction between steam and CO, under the catalytic influence of O compds. of the rare earth metals, especially Ce. The oxides are applied preferably in a finely divided or finely porous form, which is secured by heating the formed pptd. hydroxides, alone or with the addition of a binder or diluent, the gas mixt. being conducted over the product.

Ger., 284,177, Feb. 24, 1914. CHEMISCHE FABRIK BUCKAU. **Addition to 283,096 (C. A. 9, 2439).** In the **utilization of magnesium chloride liquors from the potash industry**, according to the principal patent, the liquors are heated with H_2SO_4 until all HCl is driven off, whereupon the residual soln. solidifies to a solid crystal mass, the removal of which from the vessel is attended with difficulty. This objection is met

by heating the liquors with H_2SO_4 *in vacuo*. All HCl is expelled at a low temp. The condensed HCl is much stronger, and a soln. of MgSO_4 which does not solidify remains in the vessel. Furthermore, the HCl distils over free from As , since at the low temp. employed *in vacuo*, the formation of volatile AsCl_3 does not occur.

Ger., 284,178, Apr. 29, 1913. TORFENTGASUNG STAUBER. In a furnace for obtaining ammonia, from smouldering bituminous substances at a low temp., the H_2O -tubes or chambers, provided with inlet and exit tubes for H_2O and steam, are so disposed as to divide the interior of the furnace into two adjacent chambers. The H_2O -tube system is provided above with a steam valve, through which steam can be conducted to the incandescent mass.

Ger., 284,258, Oct. 4, 1914. ELEKTROCHEM. WERKE and O. DREIBRODT. Mfg. faultless artificial or synthetic precious stones. By fusing Al_2O_3 powder or mixts. thereof with metals or their oxides, in a vertically disposed oxyhydrogen flame, in such manner that the falling powder is brought to a state of fusion at a point upon a refractory rod of fire-brick, a crystallized stone may be obtained, as the fused drops assume the form of an optical crystal, which is enlarged by subsequent additions. The flame and the rod are encased in a nonconducting chamber, the purpose of which is to prevent rapid cooling of the products. Obtained in this manner, the stones exhibit, upon polishing, marked colored striations, and often enclose gas bubbles. This objection is overcome by rotation of the refractory rod at a rate of 200 r. p. m. This axial rotation is continued until the product is cold. Uniform temp. is maintained throughout the process so that fracture of the stone on cooling is prevented. As a result of the rotation the stone assumes a cylindrical form, with a horizontal upper surface, the bubbles escape, and the striation is right-lined. The optical axis of the stone lies either in the direction of the axis of rotation or vertical thereto, which is of advantage in cutting.

Ital., 135,224, Aug. 12, 1913. U. VIGANÓ and L. SOLDI. Obtaining ammonia from molasses slops. After the extn. of the alc. from the molasses, the residual liquid is treated in a furnace, whereby a residue rich in K salts is obtained. This mass, after being drawn from the furnace in an incandescent state, is burned further *in pleno*, cooled, and crushed for the market. The N still contained in the furnace may be utilized by means of a circulation of air and water-vapor, with condensation of the resulting NH_4OH , or the NH_3 may be absorbed in H_2SO_4 ; the yield of $(\text{NH}_4)_2\text{SO}_4$ is about 20% of the theoretical.

Ital., 139,955, Feb. 24, 1914. A. BAMBACH. In a process of mfg. sulfuric acid and oxides from sulfates, preferably alk.-earth sulfates are decomposed at a high temp. with gas and air within a suitable container. The process is applicable to oxidized S.

Ital., 139,971, Feb. 26, 1914. G. ODDO. Mfg. concentrated solutions of sodium hydrosulfite by allowing concd. solns. of Zn hydrosulfite to react with NaHCO_3 .

Ital., 140,537, Mar. 18, 1914. NORSK HYDRO ELEKTRISK KVAELSTOFAKTIESELSKAB. Oxygen and nitrogen are obtained from the air by liquefaction and rectification. The air employed in the process is made to pass, after dialysis, through a suitable membrane, in order to enrich it in O.

Ital., 140,547, Mar. 20, 1914. R. FULLONI. Treatment of red bauxite, by means of HCl , to sep. the Fe, which goes into soln. The slimes left from this treatment may be similarly treated.

Ital., 141,206, Apr. 29, 1914. J. PATRK. Preparing hydrogen peroxide by distg. a simple mixt. of NH_4 persulfate, or other readily sol. alkali persulfates, with H_2SO_4 , and carefully sepg. the H_2O_2 formed.

Ital., 141,241, Apr. 17, 1914. F. HÄUSSER. In a process of absorbing rarefied nitrous gases in water, the reoxidation of the NO, resulting from the action indicated

in the following equations, is effected by passage of the gases from the first absorption, and subsequent treatments, through a long conduit, repeatedly back to the absorption app. $\text{N}_2\text{O}_4 + \text{H}_2\text{O} = \text{HNO}_2 + \text{HNO}_3$; $3\text{HNO}_2 = \text{HNO}_3 + 2\text{NO} + \text{H}_2\text{O}$.

Ital., 141,275, Apr. 16, 1914. A. CLASSEN. In a process of mfg. compounds of nitrogen, the reacting gases are subjected, under high pressure, to the action of the silent elec. discharge in the presence of catalyzers formed of metals or alloys in the colloidal state deposited on indifferent substances such as asbestos, etc. The process serves for the manuf. of both NH_3 and HNO_3 .

Ital., 142,260, May 27, 1914. R. CRUSA and R. TORCHI. In a process of deodorizing vegetable liquids or saps and exts. thereof, on a commercial scale, with the use of K salts, the liquid under treatment is heated in the autoclave with the final addition of an acid, and sepd. from the K salts by the addition of perchloric acid or perchlorates.

Ital., 142,456, June 13, 1914. K. SCHAEFER. Preparing oxygen by the alternate passage of reducing gas and steam over heated Fe. A highly heated reducing gas is passed over the Fe material, together with an excess of air (with which the impurities, S and C, are burned). When the heating has been effected, air is added; with it the Fe and the lower oxides are completely oxidized. Finally, a current of superheated steam is passed.

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

Clay products as engineering materials. A. V. BLEININGER. Bureau Standards, Pittsburgh. *Trans. Intern. Eng. Congress 1915* (advance copy).—In building brick the mortar is usually the limiting feature in strength. Porosity is a good index of the quality of bricks from any one clay, but different clays cannot be directly compared. Six different clays showed porosity of 23.0, 25.0, 26.5, 29.5, 33.5 and 40.0% when burned sufficiently in each case to give a compressive strength of 5000 lbs. per sq. in. Compression testing of whole bricks flatwise is condemned. Half bricks on edge are much better—edge testing gives results 13% lower than flat testing. In exposed structural work, resistance to freezing and thawing stresses are most important. This resistance is not a direct function of porosity. Actual freezing tests are good but laborious. Accelerated tests like Brard's (immersion in boiling soln. of Na_2SO_4 and then crystg.) show clearly when burning has developed full strength, but in comparison with freezing such tests are too severe. Paving brick, hollow tile, fireproofing, architectural terra cotta, sewer pipe, drain tile, floor tile, wall tile, roofing tile, enameled brick and sanitary ware are briefly discussed.

C. H. KERR.

Manufacture and tests of silica brick for by-product coke ovens. KENNETH SEEVER. Harbison-Walker Refractories Co. *Bull. Am. Inst. Mining Eng.* 1913, 1913-27.—The term "silica brick" should embrace only products with 94% or more SiO_2 , usually made from quartzite rock with a small % CaO added as a binder. The largest quartzite fields are Pa., Wis., Ala., and Col., given in the order of their importance. Pa. makes 75-85% of the U. S. product, mostly from quartzite of the Medina and Oneida formations in Huntingdon and Blair Cos. Typical analysis shows 97.8% SiO_2 . A hard cryst. rock like the Medina quartzite is required for a strong brick. Prepn. embraces (1) crushing to 1 to 2 in. ring, (2) wet pan grinding with the addition of 2% CaO added as milk of CaO . With 3% CaO brick is less resistant to abrasion. With more CaO , even up to 7%, strength still further decreases. There is no appreciable effect on refractoriness up to 3%, but above that the fusing point is lowered. Less

than 2% CaO does not give the required strength. The finer the grinding the greater the resistance to abrasion. In molding, the damp mix is rammed in by heavy beaters. Firing takes 9 to 12 days, with a final temp. of 1650° usually held a little over 1 day. Cooling takes about the same time. During burning, bricks take a permanent expansion of about $\frac{3}{8}$ in. per ft., due to the inversion of quartz to cristobalite directly (not through tridymite). To det. the amt. of inversion of quartz to cristobalite, 3 lots of SiO₂ brick were subjected to 1, 2 and 3 regular burns, resp., to 1540°, and also 2 lots of quartz rock received 1 and 2 burns, resp. Powdered samples were immersed in the liquid of $n_D = 1.51$ to distinguish between quartz (slow ray $n_D = 1.544$) and cristobalite (fast ray $n_D = 1.485$). Of the SiO₂ brick, the 1, 2 and 3 burn samples showed, 77.35, 82.87 and 83.98% cristobalite and the 1 and 2 burn quartz samples showed 49.5 and 68.62% cristobalite. "Thus far we have assumed the changes in cryst. form to be desirable because of their effect on the expansion of the material." Modulus of rupture on reburning showed 624, 809 and 1001 lbs. per sq. in. for the 1, 2 and 3 burn SiO₂ brick samples, resp., and the crushing strength was 4313, 4396 and 4500 lbs. per sq. in.

C. H. KERR.

U. S., 1,151,911, Aug. 31. E. C. SULLIVAN and W. C. TAYLOR. Glass for making seals of incandescent lamps, etc., is formed of SiO₂ 42, soda 19, potash 5, BaO 19 and Al₂O₃ 15%. It has a linear expansion coeff. of 0.0000135.

U. S., 1,151,942, Aug. 31. V. H. GREGORY. Glass-furnace.

U. S., 1,152,428, Sept. 7. A. T. MALM. Pyrometer tubes or combustion tubes and similar refractory articles are formed of fused alumina carrying a coating of glazing material to render them impervious to gases and with outer and inner coatings of fused Al₂O₃. The latter prevents the glazing from adhering to the support of the tube when it is heated in use.

U. S., 1,152,828, Sept. 7. W. N. MATHEWS. Glass-furnace.

Brit., 10,161, Apr. 24, 1914. H. BECKER. Crystalline glass products, resembling stone, granite, etc., are manufd. by heating the raw materials for glass-making (e. g., sand, soda, lime, clay, etc.) until incipient fusion takes place, and then removing the mass from the furnace or beyond the range of smelting temp., and coating or annealing, as usual.

Brit., 10,488, Apr. 28, 1914. A. J. DAVIS. In the manuf. of colored lenses, plates, prisms, etc., more especially for railway, shipping, lighthouse, and other like purposes, ordinary com. colored sheet glass is coated with a thin layer of a fusible silicious compd. consisting of SiO₂, red lead, borax, pearl-ash, KNO₃, or other like ingredients. The sheet is bent under heat to the required shape in a mold, during which process the cement is fused and forms a transparent coating on the glass. Molten clear white glass is then applied to the sheet and molded to the required form.

Brit., 10,983, May 4, 1914. E. MAUVILLIN and V. GUILLER. In a process of imitating mother-of-pearl in designs on glass, as in making sign boards, an iridescent surface is first produced by depositing a very thin pellicle, e. g., of nitrocellulose, upon a polished Zn or other plate which has been irregularly undulated, as by stamping. The desired design is reproduced upon a sheet of glass by means of an opaque varnish or by photography, and when dry it is coated with a granular deposit, which gives the appearance of the glass having been ground; or the design may be directly produced in the ground face of a celluloid plate. The diffusing layer may also be produced by the action of a sand-blast or of HF upon glass or mica. The glass and Zn plates are then superposed. The granular deposit may be produced from a mixt. of ether, benzene, putty, and sandarac.

Brit., 10,985, May 4, 1914. R. GREIFELT. **Lithophane porcelain ware**, such as beer tankards, milk mugs, etc., is produced by applying a highly translucent material in the required design to the modelling face of a plaster mold of the article to be produced, and then casting over it a less translucent material having a higher m. p., but the same coeff. of shrinkage. The covering material is partly removed or scooped out on a turning disk until only a thin covering remains on the translucent material, and the article is burnt and finally glazed.

Ger., 282,990, Sept. 26, 1911. P. KAEHLER. Press for mfg. corner pieces of ceramic masses.

Ger., 284,092, Apr. 4, 1914. VERTRIEBSGES. FÜR AUTOMATISCHE FLASCHENTRANSPORTVORRICHTUNGEN. Addition to 283,036. Construction and operation of automatic bottle-blowing machines.

Ger., 284,309, Mar. 27, 1914. ADLER-INDUSTRIEWERK. **Flower boxes or pots** are poured in the rough, from a mixt. of magnesite and $MgCl_2$ lye and sand, in oiled molds. After removal from the molds the box or pot is etched in a HCl soln. until a rough surface similar to that of natural stone is obtained, and the structure is porous. The acid which has penetrated is removed by washing with water.

Ger., 284,310, Nov. 26, 1912. O. FRICK. **Mfg. bricks and furnace lining** from strongly burned magnesite, with avoidance of H_2O for mixing. The MgO , obtained by burning the natural impure magnesites, is finely ground so that the enclosed particles of CaO are broken up and distributed uniformly through the mass, thereby avoiding any marked stress due to slaking. This mass is then ignited at a temp. above 550° to expel hydrate H_2O . Refined petroleum, or other completely volatile indifferent liquid, is used for mixing. The black or lining material is burned at a high temp. until no more shrinking occurs. For furnace lining the temp. of burning must be at least 1550° . The products are especially suitable for use in elec. induction furnaces. The magnesite can be used repeatedly provided the steel particles are removed. About 15–20% of fresh incompletely burned magnesite is added and mixed intimately therewith.

21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

The fusibility of coal ash in mixtures of hydrogen and water vapor. A. C. FIELDNER AND A. L. FEILD. Bur. Mines. *J. Ind. Eng. Chem.* 7, 742–7(1915); continuation of C. A. 9, 1837.—The softening temps. of 5 coal ashes were detd. in various mixts. of H and H_2O vapor from 100% H to 100% H_2O . There is a high softening temp. in pure H at one end due to the reduction of Fe_2O_3 to Fe and a similar high temp. in H_2O vapor or air at the other end due to conversion of Fe_2O_3 to Fe_3O_4 . In the range 30–70% H_2O vapor there is a more or less lower softening temp. due to reduction of Fe_2O_3 to FeO in which form it combines readily to form fusible silicates. It is shown that fuel bed conditions are such as to favor the formation of clinkers containing principally Fe^{++} . A new method of detg. the minimum softening temp. is given. In this the ash is heated in an atm. of 50% H and 50% H_2O vapor by which means the Fe_2O_3 is reduced principally to Fe^{++} . ISADOR MILLER.

Economic utilization of coal and production of cheap power. W. F. REID. *J. Soc. Chem. Ind.* 34, 775–81(1915).—R. discusses the coal resources of the world as

compared with those of England, and the various methods for the production of power.

C. A. COLE.

Thermal study of the carbonization process. H. HOLLINGS AND J. W. COBB. Univ. Leeds. *J. Chem. Soc.* 107, 1106-15 (1915); cf. *C. A.* 8, 3110.—The substances tested were heated in thin fire-clay boats, through which passed long thin silica tubes containing thermo-couples. The boats and silica tubes were inserted in a porcelain tube which was heated in an elec. furnace, the tube being placed so as to bring the boats in the center of the furnace. A coke standard was previously prepd. by packing coal in one of the boats and heating to 1100° in an atm. of N. Substances to be tested were placed in one boat and the coke standard in the other. The couples were connected in opposition to show the difference in temp. of the coke standard and the test. The heating was always done in an atm. of purified N, and the most suitable rate of raising the temp. of the coke was found to be 7° per min. It is claimed that potentiometer deflections to the left indicated a preponderance of endothermic reactions, and deflections to the right exothermic. After obtaining the heating curve of coal against a coke standard, a control expt. was made by heating the coke obtained from the coal against the same coke standard. Deflections obtained below 200° were disregarded. Below 400° cellulose showed a strong endothermic reaction commencing at 345°; this was much weakened in dehydrated cellulose and lignite, and absent in coals. Between 400 and 600° the characteristic differences of different types of coal were manifest. Oils, unsatd. hydrocarbons, higher paraffins and oxygenated compds. were produced, varying with the nature of the coal, and the thermal phenomena were varied in a corresponding degree. Between 600 and 800° CH₄ was evolved and all coals show marked exothermicity. Above 800° H was the main product of distn., the process being either thermally neutral or more probably slightly endothermic. Thermal phenomena at low temps. were marked with cellulose and coals of high O content, at high temps. with anthracite and coals of low O content.

L. W. RIGGS.

Effect of temperature and moisture on carbonization. G. E. FOXWELL. *Gas World* 63, No. 1620 (*Coking and By-Product Sec.*), 13-14 (1915).—Water vapor has two functions in the coke oven: it can act as a cooling agent or as a diluent. In the latter case the result of its action is to conserve the by-products. A little cooling may be advantageous in that it will prevent overheating and so preserve NH₃ and C₄H₄ from decompn. in passing through the hot layer of partially carbonized coal. If cooled too much the coal will be carbonized at too low a temp. and yield of NH₃ and other products will suffer. The yield of coke continually decreases as the % of added H₂O in the charge increases. Under 9% the decrease is rapid and above that point it is slower. At about 10 or 11% the moisture has attained its max. as evidenced by the falling off in CO after 13%. Up to about 9% the effect is to protect the NH₃ from decompn.; above this % the charge becomes too cool for the max. formation of NH₃ and the yield of NH₃ decreases. This same moisture content of 9 to 10% still seems to bear some essential relationship to the yield and comp. of the hydrocarbons. High moisture decreases the C₄H₄ content of the gas and as the C₄H₄ decreases, C₂H₂ increases. This increase is probably due to the lowering of the temp. in the oven. Moisture exerts a protective influence over the tar, the quantity of which increases with the increase of H₂O content. The general conclusion to be drawn from well-known facts and from lab. expts. seems to be that a temp. of about 900° and a moisture content of as nearly 9% as possible will give the best results.

M. L. TROWBRIDGE.

Briquetting and tar distilling plant of the Nürnberg gas works. RUDOLF TERHAERST. *J. Gasbel.* 58, 300-1 (1915).—The plant has operated since 1912. Egg-shaped briquets are made from coke breeze and coal-tar pitch. To supply the pitch there was installed a tar still, which not only served the briquetting plant but also re-

distd. wash oil for the naphthalene washers, and furnished a tar oil which could be used for lubricating the exhausters. These last two alone yielded a profit on the distn. plant. The pitch was pulverized and stored in bins, as was also the coke breeze. From these bins coke and pitch were withdrawn by feeding tables, heated to 200° , by superheated steam in a mixer, and then fed to the press. The amt. of pitch could not be varied much without producing either crumbly briquets or briquets that stuck in the press. Briquets were made with 15,000 kg. pressure with 8% pitch, and had a crushing strength of 80 kg. along the short axis. The output of each machine was 25 to 30 metric tons per day. The briquets are used under the boilers or sold for domestic heating. Used in the water-gas plant, the pitch assists in the carburization. Costs are about 30 pf. for 100 kg. without allowance for material. Previously the breeze was burned in the plant for steam raising, but has to be supplemented by coal. Now the same amt. of breeze, briquetted, furnishes all the steam and leaves a surplus for sale. In distg. the tar the temp. is run to $350-60^{\circ}$, with vacuum toward the end. 53% pitch and 47% oil are obtained.

W. L. BADGER.

Report of the committee on manufacturing, Iowa District Gas Association. ANON. *Am. Gas Light J.* 103, 131-2(1915).—The following matters were discussed: Water-gas machine results in a small works; different kinds of oxides; the most economical way to heat the water in holder in a small plant to prevent freezing. In regard to water-gas machine results the following items are recommended: Maintenance of the temp. of the superheater within $1,300-1,400^{\circ}$ F.; avoidance of high temp. at the top of the carburetor; equipment of the machines with pyrometers; the use of a good grade of coal, and the maintenance of deep fuel beds in the generator; operation of the machine during the period that the most gas is being sent out to avoid stand-by losses; removal as soon as possible of the gas in the relief holder to the storage holder to prevent hydrocarbons from dropping out; the use of a gas analysis app. to det. the quality of the gas; proper care in the distribution of tar as a waste product. A good iron oxide is prepd. by mixing wet shavings or cobs with cast iron borings and salt, and left to cure. Particular attention should be paid to the scrubbing and condensing, as oxides rapidly deteriorate by being coated with tar. Oxide should not be discarded until it contains 60% of S. Holders are prevented from freezing by circulating water from the tank through the condenser back to the cups and tank.

P. J. COLE.

The composition of natural gas used in twenty-five cities. G. A. BURRELL AND G. G. OBERFELL. *Bur. Mines, Tech. Paper* 109, 1-20(1915).—Methane is the predominant constituent. No H_2 , O_2 , CO, H_2S , or olefin hydrocarbons were found. Higher paraffins were present. Different strata in the same region may yield gas with different characteristics. B. t. u. values range from 740 to 1312. Explosive limits are 4.92 to 11.50% gas. Ignition temp. is 550 to 750° . Compn. is const. for long periods. Ra Em and He have been found in the gas. Natural gas has no toxic effect on men or birds but acts as diluent of O_2 . When % O_2 falls to 8 suffocation occurs.

BERMAN.

Waste heat recovery in gas plants. ERNST SCHMIED. *J. Gasbel.* 58, 327-9(1915).—The plant in question consists of 3 Munich chamber ovens and 3 vertical ovens (both 8's). The steam demands on the plant in very cold weather, when the holder water has to be heated, are excessive. The sources of heat considered are the hot gas, the hot coke, the stack gases, and the radiation. The first is dismissed as being too small for the installation necessary to recover it. At present the coke is all quenched; and it is calcd. that sending what is needed directly to the producers without quenching would save 75,000-150,000 cal. per hr. The stack gases should leave the regenerator at 400° , and between this and $250-300^{\circ}$ (necessary for draft) there is too little fall available to be worth while. At S.'s plant the gases left the regenerator at 730° , and the question

was whether to improve the firing so as to have no after-combustion in the regenerators and hence cooler stack gases, or to use the heat under existing conditions. In this case the latter was preferable. It is also suggested that by covering the top and sides of the oven blocks with pipe coils large amts. of heat otherwise lost by radiation would be recovered, but not as high-pressure steam. S. recommends a waste-heat boiler on top of the vertical ovens to take part of the heat of the gases of combustion before they go to the regenerators, pipe coils in the flues to take up heat from the gases leaving the regenerators, and coils on the outside of the blocks as above.

W. L. BADGER.

The production of sulfate of ammonia in 1914. ANON. *Am. Gas Light J.* 103, 161-4 (1915).—Statistics are given and discussed.

E. J. C.

U. S., 1,151,676, Aug. 31. H. FOERSTERLING. **Generating steam and producer gas.** Currents of air and steam are continuously and simultaneously directed through the pipes 3 and 17, 6, resp., into the fuel bed of the producer 1. H_2O is preheated in the jacket 2 of the producer and is then converted into steam in the boilers 7, 9 which are heated by the gas generated in the producer. High-pressure steam in excess of that required in the producer is generated in the boiler nearest to the producer. From the boilers, the producer gas passes through a scrubber 11 to a gas engine 12. Circulation of the H_2O is maintained by pumps 14 and 16. 18 is a steam engine for utilizing surplus steam.

U. S., 1,151,825, Aug. 31. T. RIGBY. **Removing water from peat.** The peat is heated until it is wet-carbonized, then cooled to about 70° by heat interchange with fresh peat, filter-pressed while still heated and the warm effluent from the filtration is used in the heat-regenerator to heat fresh peat. Cf. C. A. 9, 369.

U. S., 1,152,869, Sept. 7. C. F. ZEEK. **Apparatus for making water-gas.**

Brit., 9,849, Apr. 21, 1914. W. J. MELLERSH-JACKSON. In the distillation of coal in vertical retorts provided at their bases with a body of coke, the working temp. is high enough to raise the coke to incandescence, and steam is passed through the coke continuously during distn. to produce water gas and prevent deposition of C on the walls of the retorts. Before charging coal on to the bed of coke, the retorts are heated to a temp. of from 1800 to 2300° F. Steam is supplied by pipes, and the body of coke, after starting the operation, is supplied from the retorts.

Brit., 10,059, Apr. 23, 1914. J. MACKENZIE. **Ammonium sulfate** is obtained by treating moist distn. gases, containing NH_3 and H_2S , with N oxides or oxy-acids, which may be obtained by treating $NaNO_3$ with H_2SO_4 , so as to oxidize the H_2S to H_2SO_4 , which immediately combines with the NH_3 . Any excess of N oxides is absorbed in H_2SO_4 , and subsequently recovered for use again.

Brit., 10,284, Apr. 25, 1914. L. L. SUMMERS. A coke oven of the kind described in 6,504, 1910, and 7,049, 1910, is divided by longitudinal walls of relatively light construction into a number of cells in which the charge is compressed equally and moved forward simultaneously by the connected reciprocating floors. Heating flues are formed in the side walls, roof, and partition walls, preferably by tiles, each having

formed therein a portion of a flue, and the abutting faces of the tiles are jointed to allow of expansion and contraction, as by rib-and-groove joints. Cf. C. A. 8, 3852.

Brit., 10,928, May 4, 1914. STUART AMERICAN PRODUCTS CO. In a process of carburetting air with crude oils or low-grade hydrocarbons, of the kind wherein the oil is vaporized by heat and the vapor mixed with air, the mixt. being led to a settling tank from which it is passed upwards through a filtering medium, the mixt. as it enters the settling tank impinges against a deflecting surface and is given a downward motion. The air supply is admitted to the pipe conveying the mixt. to the settling tank at some distance behind the delivery end of the vapor supply pipe, and, in some cases, the air may be admitted after or both before and after the vapor has passed through the filtering medium.

Brit., 10,960, May 4, 1914. V. GAUMER. Preventing back-firing in tanks for storing inflammable liquids and gases, and in lamps, carburetors, etc., by providing an attachment for the inlets and outlets, comprizing a series of superposed disks, alternately corrugated and plain.

Brit., 10,972, May 4, 1914. H. BURGI and C. H. TENNEY. In a continuously working vertical retort, the gases produced in all parts of the retort are withdrawn together from an intermediate zone where the temp. is such that the hydrocarbons are fixed without the production of lamp-black. Enriching hydrocarbons may be fed to the same zone.

Fr., 465,022, July 11, 1914. WETCARBONIZING LTD. Process of dehydrating peat (wherein the H_2O has been liberated by a heat treatment such as wet carbonization), consisting in subjecting the material, in relatively thin layers, to the action of a slight difference of pressure, as by aspiration, by action of a light pressure, or by both means. After the mass has been brought in this manner to a suitable consistence (say with 78-80% H_2O), it is passed through a press or exposed in a finely divided state to the action of a hot gas to complete the drying. Cf. C. A. 8, 1663.

Fr., 475,023, July 11, 1914. WETCARBONIZING LTD. In a process of collecting peat from wet or badly drained peat beds, applicable especially in combination with heat treatments designed to render the H_2O expressible, and particularly where the peat is to be transported in the form of pulp by pipe conduit, the extrn. of the peat is effected in a series of separate excavations, the peat after heat treatment being returned to the excavation for further treatment.

Illustrations of the types of still-heads used are given and also many tables of data showing the results obtained with each form of app.

ISADOR MILLER.

Improvement of high boiling petroleum oils and the manufacture of gasoline as a by-product therefrom by the action of aluminum chloride. A. M. McAFEE. *J.*

Ind. Eng. Chem. 7, 737-41(1915); cf. *C. A.* 9, 2147.—Description of the author's process. Crude oil is first heated to drive off any gasoline and H_2O present and anhydrous $AlCl_3$ added to the residue, after which the mass is boiled at $500-550^\circ F.$ for 24 hrs. Any ordinary still can be used. Between the still and the final condenser are 2 air-cooled condensers in series; these separate the low and the high boiling oils. The volatilized $AlCl_3$ and its compds. are returned to the still. Vapor enters the final, water-cooled condenser at a temp. of $300-350^\circ F.$ The product here is a mixt. of gasoline, solvent oil and kerosene, all water-white and sweet-smelling. Results on 3 typical crudes (Texas, Oklahoma and Caddo) are given as illustrative of the process. After a time the $AlCl_3$ loses its activity and is converted into a coky mass. It is recovered from this by first removing the bulk of the oil and then extg. with H_2O or steam to obtain a concd. soln. of hydrated $AlCl_3$. This last has no catalytic action but if heated breaks up into Al_2O_3 and HCl (gas). The Al_2O_3 is then treated with C and HCl (gas) at high temp. and $AlCl_3$ recovered. Or, the coky mass is heated to redness in an atm. of Cl. Also in *Met. Chem. Eng.* 13, 592-7(1915)

ISADOR MILLER.

The solid constituents of the mineral oils. J. MARCUSSEN. Berlin. *Chem. Ztg.* 39, 581-2, 613-6(1915).—The solids consist of 2 classes, hydrocarbons and compds. containing O. The latter consist of acids (in negligible amts.), resins and asphaltic substances. The asphaltic substance sepd. with alc.- Et_2O , or fuller's earth, or blood charcoal, m. below 100° and is resolved, when treated with light benzene, into sol. and insol. portions. The sol. portion is the "mineral oil resins" which form a transition group between the hydrocarbons and asphalts. Nitration showed that both the resins and asphalts are apparently poly-cyclic compounds, which may be oxidized by $KMnO_4$ to acids which form characteristic alkali salts. The 1st stage of oxidation of the hydrocarbons produces the resins and further oxidation results in asphaltine. The 2nd step occurs slowly at ordinary temp., rapidly and completely at 120° , or by auto-oxidation of the satd. and unsatd. hydrocarbons, the latter usually being polymerized at the same time. S plays a similar role. The solid hydrocarbons are partly crystalline, resembling paraffins, partly amorphous, resembling ceresins. Ceresin is shown by several methods to consist chiefly of isoparaffins. The organic theory of the formation of petroleum is briefly discussed. Cf. *C. A.* 8, 1868, 1870. J. H. MOORE.

A quick method for testing the non-staining quality of textile oils by means of the Cooper-Hewitt quartz lamp. T. T. GRAY. *Oil, Paint and Drug Rep.* 88, No. 6, 19(1915).—Test pieces of tape are treated with the oils and placed 6 in. below the Cooper-Hewitt quartz tube. After $\frac{1}{2}$ hr. the tapes are examd. for yellow-brown stains. A Russian petroleum oil, which develops no stain, is used as a standard.

E. W. BOUGHTON.

Weighted silk. KARL HOMOLKA. Limbach. *Färber-Ztg.* 26, 46-7(1915).—Silk weighted by the Zn phosphate-silicate process becomes brittle and discolored when stored, subjected to perspiration, or to the action of NaCl solns. or of benzine. The exact causes for these changes are not known, but presumably oxidations caused by photochem. processes and liberation of mineral acids as a result of the change of the weighting compds. from the colloidal to the cryst. condition, are involved. If the silk is impregnated with 8-10% HCO_2NH_4 soln., and then squeezed and dried, considerable improvement in the keeping qualities is effected. Easily oxidizable substances such as thiourea and hydroquinone do not preserve silk weighted with Sn compds. Hydroxylamine hydrochloride used in 1-1.5% soln. gives satisfactory results.

W. F. FARAGHER.

Injury of vegetable fibers during bleaching with bleaching-powder solutions in the presence of metals. P. WEYRICH. *Z. ges. Textilind.* 18, 176-7, 819; *Chem. Zentr.* 1915, I, 1288-9.—White (*J. Soc. Chem. Ind.* 22, 132(1903)) observed weakening of vegetable fibers during bleaching in solns. of bleaching powder when the fibers were in contact with certain metals. Briggs also calls attention to a similar phenomenon in the presence of Cu (*J. Soc. Chem. Ind.* 30, 397(1911)). It is known that the hydroxides and oxides of certain metals, such as Hg, Cu, Co, Ni and Fe, catalyze the decompn. of hypochlorite solns., O being liberated. This O converts cellulose into oxycellulose which is brittle. In the case of alloys, less is known in this regard. It is possible that some alloys do not act catalytically upon hypochlorites, and that these would be suitable for use in the construction of bleaching app. A number of com. alloys were tested by W. by placing strips, which had been cleaned carefully, into 1° Bé. soln. of bleaching powder (3.343 g. available Cl per l.). The areas of the surfaces of all strips were the same, and the strength of the bleaching-powder solns. was tested at regular intervals. Borscher's alloy, which is a Cr-W steel, had the least action on the soln. Vegetable fibers were wrapped around pieces of the alloys and metals and were then immersed in the soln. for 6 hrs. Tests for oxycellulose were made after the soln. had been removed by rinsing. Cu, bronze, Ni, Co, Mn, manganin, cast iron, Cr steel, and Zn caused formation of considerable oxycellulose; Pb and Cd were less active, and Borscher's alloy, Sn, Bi, Cr and Al were practically without action.

W. F. FARAGHER.

The Peufailit method for retting flax. A. DURAND. *Bull. soc. encour. ind. nat.* 121, 153-86(1914); *Bull. Agr. Intelligence* 6, 622.—The following methods

of retting flax have been carefully examd.: Legrand-Vansteenkiste, J. B. Cousinne, Emile Feuillet (¹), Peuffaillit. The Feuillet process has been already adopted on a large scale. As distinct from the others, the Peuffaillit process is exclusively chemical and based on the action of hydrocarbons under pressure in the presence of water vapor. The bundles of flax are ranged in metal baskets, two of which are placed in one autoclave. After exhausting the air, the autoclaves are filled with water. Heavy petrol is then injected in the proportion of 4% by wt. of the flax. The pressure is gradually increased to 35 lbs. per sq. in. and maintained during 8 hrs. The autoclaves are emptied under pressure and the strands of fibers separate intact. The flax is then dried and beaten with rotating cylindrical beaters and the fiber is so completely sepd. that stripping is unnecessary. After combining the process is completed. The proportion of tow is reduced to a minimum. The fiber has a characteristic color of its own, and is uniform and tough. The smell of petrol is perceptible in the tow, but is very slight in the fiber and disappears completely at the first combing. A by-product is obtained from the gummy substance remaining in the autoclaves, the sale of which should cover a considerable part of the expenses. This method is also applicable to the extrn. of other fibers, such as hemp, ramie, palm and papyrus. E. J. C.

U. S., reissue 13,969, Aug. 24. A. STOCK and F. HZIM. **Bluish triphenylmethane dye.** See original pat. 1,065,405 (C. A. 7, 2858).

U. S., 1,151,416, Aug. 24. G. A. STRENGER. Composition for removing stains from textile fabrics; a dry powder formed of $\text{Na}_2\text{S}_2\text{O}_4$ 30, tartaric acid 10 and NaHSO_4 60 parts.

U. S., 1,151,487, Aug. 24. B. LÖRWE. Artificial silk is made by drawing a thread or filament of natural silk through a bath of ingredients for forming artificial silk, through the die *a*, projecting a jet of artificial silk material from the nozzle *d* against the thread or filament as it comes from the die, twisting the composite thread and finally treating it with a solvent such as a hot dil. soln. of soap and Na_2CO_3 to loosen the strands so that they do not adhere to each other.

U. S., 1,151,628, Aug. 31. K. THIES. A vat dye is made by treating 2,5-dianilino-3,6-dichloroquinone with $\text{Na}_2\text{S}_2\text{O}_4$ or S and NaOAc and alc. or pyridine. It is a nearly black powder, almost insol. in organic solvents, sol. in H_2SO_4 with a dark bluish violet color, and dyes wool a fast blackish tint. Similar dyes, dyeing olive-gray to blackish tints, are obtained from the condensation product of chloranil and *p*-toluidine.

U. S., 1,151,916, Aug. 31. J. T. WOOD. Cop-holder for dyeing apparatus.

U. S., 1,151,917, Aug. 31. J. T. WOOD. Perforated beam or spool for dyeing apparatus.

U. S., 1,152,159, Aug. 31. E. FEUILLETTE. Apparatus for steeping or retting flax, hemp, etc.

Brit., 10,085, Apr. 23, 1914. CHEM. FABRIK GRIESHEIM ELEKTRON. Monoazo and diazo dyes are obtained by combining diazo or tetraazo compds. of the anthraquinone series with arylides of 2,3-hydroxynaphthoic acid; the dyes may be prepd. in substance or on the fibers.

Brit., 10,378, Apr. 27, 1914. AKT.-GES. FÜR ANILIN FABRIKATION. 1-Amino-4-arylaminoanthraquinone-2-sulfonic acids, which dye wool greenish blue shades, are obtained by treating 1-amino-4-haloanthraquinone-2-sulfonic acids with aromatic amines in presence of H_2O and of Cu or Cu compds.; acid fixing agents may be present or not. The product from 1-amino-4-bromoanthraquinone-2-sulfonic acid and *p*-toluidine is described in examples.

Brit., 10,527, Apr. 28, 1914. T. D. MORSON and C. S. ROY. Fabrics for filter cloths are woven with warp and weft of threads formed by spinning and twisting fibers of ordinary soda or Pb glass or like vitreous silicious material.

Fr., 475,010, Jan. 12, 1914. CASSELLA & Co. Mfg. vat dyes by heating 1-amino-2-methylantraquinone and an aromatic diamine, with S at an elevated temp.

Fr., 475,014, Jan. 13, 1914. CASSELLA & Co. Mfg. yellow sulfine dyes by heating at elevated temps. the *N*-alkyl-, *N*-aralkyl-, or *N*-acyl-carbazoles, with S and with or without the addition of benzidine or other substance having a similar action.

Fr., 475,049, Jan. 13, 1914. A. and J. BECHETOILLE. In a process of applying metal to textiles, the material is subjected to electrolytic action in one or more baths containing a metal or a metallic salt, and after rinsing the metal is fixed on the fiber by means of HCHO or a like fixing agent.

26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

Standard specifications for the purity of raw linseed oil from North American seed. ANON. *J. Ind. Eng. Chem.* 6, 164(1914).—The specifications adopted by the Am. Soc. for Testing Materials are given. E. J. C.

Linoleum cement. K. MICKSCH. *Kunststoffe* 5, 181-2(1915).—A brief discussion of the comp. and desirable properties of mixts. for cementing linoleum to different surfaces. F. W. SMITHER.

The resin industry in Spain. ITURRALDE Y ELORRIETA. *Rev. de montes* 39, 3-11(1915).—Production statistics. E. J. C.

U. S., 1,151,700, Aug. 31. M. E. McDONNELL. **Painting metal car bodies.** Successive layers of paint are applied which contain no artificial driers and each coat is heated to 120° for 3 hrs. before applying the next coat. After painting, successive coats of varnish, also free from artificial driers, are applied and dried at 52-65°.

U. S., 1,151,701, Aug. 31. C. MACNICHOL. **Painting cement or concrete structures.** The surface of the cement is coated with a mixt. formed of ZnO 2, ZnSO₄ 6, glue soln. 2 parts and coloring materials and oil paint is applied over this coating. The ZnSO₄ reacts to form ZnO and CaSO₄ and fill the pores of the cement treated.

U. S., 1,152,693, Sept. 7. L. V. BARTON and W. P. THOMPSON. **Mixing apparatus for making white lead** by the reaction of PbO, H₂O, CO₂ and a catalyzer, *e. g.*, HOAc or Pb(OAc)₂.

Brit., 9,292, Apr. 14, 1914. KARPEN & BROS. **Phenol-formaldehyde condensation products** are prepared by heating together, under practically anhydrous conditions, a methylene compd., a phenolic compd., and either a phenolic compd. different from the first phenolic compd. and having an alkylated OH group in the mol., or Me benzoate, or Ph Me ketone. Hydrobenzamide may be used instead of a methylene compd. In an example, a mixt. of phenol, anisole, and hexamethylene-tetramine is heated in an open vessel. The first product of the reaction is a viscous material, which solidifies on cooling and, on further heating with or without pressure, is converted into an insol. infusible solid. Alc. or other solvent may be added to the mixt. to control the reaction, and also to dissolve the fusible resin formed in the first stage. The product may be used for insulating purposes, and as a varnish, or mixed with PbO, sand, etc., as a paint or coating, or as a binder, *e. g.*, for abrasive material, in which case the reaction mixt., after a short heat treatment, is mixed with Al₂O₃, and the mixt. baked.

Brit., 9,926, Apr. 22, 1914. RUDGE-WHITWORTH, LTD., and H. L. HEATHCOTE. **In coating metals**, phosphate coatings such as are described in 8,667, 1906, are treated with a drying oil, lacquer, or varnish, capable of reducing the friable nature of the coating and of entering into combination with matters concerned in or arising from rusting. Linseed oil, with or without coloring matter in soln. or suspension, is applied to the surface by dipping or spraying, and the article is stoved at 300-400° F.; the treatment may be repeated, or followed by enamelling, etc. Instead of linseed oil, celluloid varnish may be applied, and the stoving effected at a temp. not exceeding 110° F.

Brit., 10,497, Apr. 28, 1914. S. SCHWIMMER. **A solvent for removing paints, lacquers, and varnishes** consists of a mixt. of C₂H₂Cl₄ with 1 or more halogenized hydrocarbons or halogenized substituted hydrocarbons, with or without substances

such as paraffin, tar oils, aniline, or colophony, for preventing the rehardening of the softened coating. The halogen derivs. mentioned are C_6H_5Cl , C_6H_4Cl , CCl_4 , CBr_4 , C_6H_5Cl , and halogenized amines, phenols, etc., such as chloroaniline. It is stated that the addition of acetic anhydride is frequently necessary in known paint-removers in order to increase their effect, but this addition is not necessary in the mixts. according to the present invention. Cf. C. A. 8, 2818.

27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

Preparation of the Wijs iodine solution. NIEGEMANN AND KAYSER. Cologne. *Chem. Ztg.* 39, 491-2(1915).—This is a reply to Dubovitz (C. A. 9, 388). A review is given of the various methods of prepn. recommended since the soln. was first described by Wijs in 1898.

J. H. MOORE.

Determination of ricinic acid in oil preparations. FR. ERBAN. Vienna. *Seifen-fabr.* 35, 578-81, 598-600(1915); cf. C. A. 8, 2818; 9, 1255, 1400.—The complete analysis of a weakly sulfonated Turkey red oil (made by using 25 parts $66^\circ H_2SO_4$ per 100 of castor oil) is described in detail, including detns. of neutral fat, organic and inorganic SO_4 , total fat by the paraffin cake and the ether methods, titration of total fat, sol. fatty acids and their titration and (qual.) glycerol. From these analytical data numerous calcns. are shown.

P. ESCHER.

The deodorization of olive oil. G. BARRION. Régence de Tunis, Protectorat français, Direction générale de la colonisation, *Bull.* 18, No. 80, 573-8(1914); *Bull. Agr. Intelligence* 6, 461-2.—The methods in use for refining lower grade oils do not succeed in freeing the oil from its unpleasant rancid flavor. B. recommends filtering the oil through animal charcoal to decolorize it, followed by the neutralization of any acids which are present and treatment with steam at reduced pressure in a closed vessel. The rancidity products, being more volatile than the oil, are carried off by the current of steam. The oil left behind has no unpleasant smell, but is insipid and non-aromatic; these defects are remedied by mixing it with unrefined oils.

E. J. C.

The composition of palm kernel and coconut oil. A. HEIDUSCHKA. *Z. angew. Chem.* 28, I, 304(1915); cf. C. A. 9, 1400.—H. doubts the correctness of Elsdon's views regarding the comp. of the above fats. The oleic acid content of the fat by no means coincides with the I no., also the high content of palmitic and stearic acid obtained by E. is striking. Numerous exams. of these fats by H. have shown them to contain at a max. only traces of these acids. It is also stated that the sapon. equiv. of the two fats given by E. are unusual, especially the proportion of the two sapon. equiv. to one another.

H. R. GUNDLACH.

Copra drying. C. W. HINGS. *Philippine Agr. Rev.* 7, 323-6(1914).—The Philippines supply about $\frac{1}{3}$ of the world's output of dried copra. Modern methods of drying and extn. are not used and the greater part of the copra produced is of poor quality. The objectionable dark color is caused by long drying and the large amt. of H_2O retained favors the development of molds and bacteria. The proper method of drying is described. The % of oil in the fresh meat usually runs from 30 to 45%. The % remaining in the dried product is largely governed by the % of remaining H_2O . Oven-dried material will contain 70-80% of oil. Two processes, the hydraulic and the continuous, are commonly used in extg. the oil. The former usually gives higher extn. but is slower in operation than the latter. The press cake makes a valuable cattle feed and also an excellent fertilizer.

E. W. BOUGHTON.

Manufacture of Turkey red oils (SCHEPP) 25.

U. S., 1,151,002, Aug. 24. C. ELLIS. An edible fatty product is prepd. by polymerizing fish oil or whale oil (with or without addition of corn oil or cottonseed oil) by heating to 250° for 12-18 hrs., in H, without a catalyzer and then heating with H and a catalyzer for a shorter time.

U. S., 1,151,003, Aug. 24. C. ELLIS. A catalyzer for hydrogenating oils and fats is prepd. by depositing Ni electrolytically on charcoal, graphite or metal. Small amts. of Cu, Zn or Ti may be deposited with the Ni. Cf. C. A. 8, 1025.

U. S., 1,151,045, Aug. 24. W. D. RICHARDSON. Hydrogenating oils or fats with a catalyst produced by electrolytically disintegrating Ni in ether or other fat solvent.

U. S., 1,151,523, Aug. 24. J. J. HOOD and A. G. SALAMON. Decolorizing mineral or vegetable oils. The oil, e. g., cottonseed oil, is dissolved in light petroleum spirit, filtered through powdered, freshly ignited MgO until completely decolorized, and then the petroleum spirit is distd. from the oil.

U. S., 1,151,718, Aug. 31. W. D. RICHARDSON. A catalyzer for use in hydrogenating oils and fats is made by reducing Ni oleate with H under pressure while it is dissolved in an oil or fat. Oleates of Cu, Co or Fe may be similarly reduced.

U. S., 1,152,023, Aug. 31. O. T. JOSLIN. Purifying catalytically hardened or hydrogenated fats or oils. The material is treated with at least its own vol. of a solvent, e. g., EtOH or MeOH, which will dissolve impurities such as fatty acids but will have but little solvent action on the hydrogenated oil or fat itself. After thorough mixing, the soln. of impurities is sepd. by gravity and the small amt. of residual solvent is removed from the purified material by volatilization.

U. S., 1,152,591, Sept. 7. R. F. BACON and B. H. NICOLET. A catalyst for hydrogenating oils and fats is made by impregnating kieselguhr, pumice or other finely divided carrier with NaOH and Na aluminate, adding a Ni(NO₃)₂ soln. to ppt. Ni(OH)₂ and Al(OH)₃ and reducing the Ni at 350-450°.

U. S., 1,153,167, Sept. 7. E. KOCHENDOERFER. Perborate soap is made by mixing comminuted dehydrated soap with Na perborate and subjecting the mixt. to pressure sufficient to melt it into a solid homogeneous mass.

Brit., 10,601, Apr. 29, 1914. R. T. H. WERLEMAN. In a process of extracting oils from nuts, the kernel or flesh of coconuts and other nuts is grated with a small quantity of H₂O, and the creamy liquid is sepd. from the residue and allowed to stand. The thick cream which rises to the top is boiled, and subjected to pressure to sep. oil.

Brit., 10,863, May 2, 1914. NAAMLIOOZE VENNOOTSCHAP ANT. JURGENS, VEREENIGDE FABRIEKEN. In processes for cooling hot or molten fats, emulsions, etc., in which the material is taken up by a rotating feeding cylinder and conveyed to the surface of a rotating cooling cylinder, the 2 cylinders are arranged close together but not in contact, and the layer on the feeding cylinder is regulated so that it is a little thicker than the distance between the 2 surfaces, and is conveyed to the cooling cylinder by a spreading or smoothing action. The distance between the cylinders is adjustable, and they rotate preferably in the same direction, the speed of the feeding cylinder being greater than that of the cooling cylinder. The fat, etc., is maintained in a molten condition until it reaches the cooling cylinder.

Ital., 132,238, July 12, 1913. OELWERK BERLIN G. M. B. H. In a process of deodorizing fish oil and the fatty acids derived therefrom, the crude materials are treated with 20-50% by wt. of benzenesulfonic acid in soln. in mineral acids. After standing for a short time, the product is worked up to a smooth mass which is odorless.

Ital., 134,086, May 2, 1914. W. PUCHS. In a process of mfg. catalyzers for reducing liquid fatty acids and their glycerides, inorganic compds. of base metals are subjected to the action of a reducing gas, in a vessel, under a layer of the oil, and under pressure.

Ital., 134,087, May 2, 1914. W. PUCHS. Reducing unsaturated fatty acids and their glycerides by means of strongly heated H acting on the moderately heated acids or glycerides. The action of the H can be increased by means of chem. active rays.

Ital., 138,942, May 5, 1914. M. PADOA and C. G. DALLA. Deodorizing and decolorizing chrysalis oil by passing a current of air or H, or a mixt. of these gases, at 140–250°, through the oil, to which may be added a catalyzer. The decoloration of the oil, which becomes brown as a result of the treatment, is effected by shaking with dichromate and H₂SO₄. The oxides of Ni, Co, Fe, Mn, Cu, Pb, Ce, etc., are specified as suitable catalyzers.

Ital., 140,846, Apr. 4, 1914. M. PADOA and C. G. DALLA. Deodorizing fish oil, and the like, by heating it in the autoclave at 150–250° with an alk. substance or a substance becoming alk. during the treatment.

28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

Variation in the sugar content of beets in the first year of growth. O. MUNERATI, G. MEZZADROLI AND T. V. ZAPPAROLI. *Stas. sper. agr. ital.* 48, 85–136(1915).—At 12 different stages of growth from June 10 to Dec. 12, samples representing about 100 beets each time were harvested; the weight of roots and leaves detd. and the sugar polarized. Beginning with 6.62% sugar, the percent of this constituent gradually increased up to the 9th of Nov. to 15.8% and then decreased to 13.6% in Dec. There was no regularity in ash and total N content during this period; the injurious N ("schädliche" N of Herzfeld-Andriik) gradually decreased. No conclusions are drawn from the ratio wt. leaves/wt. roots and the % of sugar in the roots. The repeated stripping off of leaves caused a decrease in sugar content. Even a single stripping off of leaves caused a decrease in sugar accumulation. J. A. LECLERC.

Absorption of fertilizers in different growth phases of the sugar beet (CALZOLARI)
15.

U. S., 1,152,458, Sept. 7. W. H. WAGGONER. Apparatus for bleaching cane juice, etc., by treatment with SO₂.

Aust., 4,250, May 9, 1914. B. TURKA. App. for the dry separation of sugar saps.

30. RUBBER AND ALLIED SUBSTANCES.

R. T. STOKES.

Proteins in rubber and in rubber latex. F. FRANK. *Gummi-Ztg.* 29, 196–8(1914); see C. A. 9, 2003. RAXLEY F. WEBER.

Rubber solvents in war time. F. FRANK AND E. MARCKWALD. *Gummi-Ztg.* 28, 1897–8, 1978–9(1914); 29, 59(1915).—Xylene and the derivs. of the paraffin hydrocarbons are the most promising substitutes for the low boiling hydrocarbons usually employed. Lab. expts. show that the addition of EtOH (5%) to the solvent greatly

decreases the time required for soln. of the rubber and the viscosity of the resulting soln. In consequence, less solvent is needed. Practical tests of the use of alc. as a means of saving solvent are urged on the manufacturers of rubber goods.

RAXLEY F. WEBER.

U. S., 1,149,577, Aug. 10. K. GOTTLOB. **Synthetic caoutchouc** is prepared by polymerizing isoprene or similar hydrocarbon in a dil. aq. soln. of egg albumen, blood serum or milk, while in the form of an emulsified mixt., by heating for several weeks at 60° and then sepg. the caoutchouc-like product from the albumen by coagulation. The product resembles natural rubber. Starch or gelatin may be substituted for albumen.

U. S., 1,149,580, Aug. 10. F. HOFMANN and K. GOTTLOB. **Vulcanizing rubber.** The rubber before vulcanization is mixed with about 1-2% its wt. of acetaldehyde-ammonia compd. and the vulcanization is then effected by heating with S in the usual manner. The acetaldehyde-ammonia compd. shortens the time required for vulcanization. NaNH_2 and *p*-phenylenediamine have a similar effect.

U. S., 1,151,948, Aug. 31. F. W. HERBOLD. **An elastic solid which may be used as a substitute for rubber** is made by mixing a fatty material such as castor oil or fish oil with CCl_4 or other inert solvent, treating the mixt. with Cl or Br, driving off the solvent, removing the HCl or HBr which has been formed in the material by a current of CO_2 , heating with S and washing.

U. S., 1,152,372, Aug. 31. T. W. MILLER. **Seamless rubber articles** (e. g., gloves) are formed by depositing successive layers of unvulcanized rubber on a form and vulcanizing each layer before applying the next.

U. S., 1,152,834, Sept. 7. R. B. PRICE. **Vulcanizing rubber articles such as shoes, tires or hose.** The rubber composition is formed into shape after mixing with the S required for vulcanization and is then heated in direct contact with a body of fusible alloy or glycerol, CaCl_2 soln. or other material which has an affinity for moisture and which is fluid at the vulcanization temp. Pressure is maintained on the article to retain its desired shape during vulcanization. The use of CaCl_2 , etc., prevents ingress of moisture during the process.

U. S., 1,152,835, Sept. 7. R. B. PRICE. **Vulcanizing rubber tires, hose, etc.,** by heating under 500 lbs. pressure or more per sq. in. while immersed in a body of CaCl_2 soln. or a mixt. of talc and glycerol, to produce a very compact homogeneous product.

U. S., 1,152,836, Sept. 7. R. B. PRICE. **Vulcanizing fabrics coated with rubber composition** while the coating is compacted and firmly united to the fabric by suction.

U. S., 1,152,837, Sept. 7. R. B. PRICE. **Vulcanizing rubber articles such as boots or shoes.** The material is first warmed somewhat, then is heated to a temp. above the vulcanization temp. and then subjected to the vulcanization process. The intermediate heating serves to cause only superficial vulcanization.

U. S., 1,152,838, Sept. 7. R. B. PRICE. **Vulcanizing sheet rubber.** The sheets are coated with glycerol to prevent them from adhering to each other during vulcanization and are then placed one on another in a pile and vulcanized while so piled.

U. S., 1,152,935, Sept. 7. J. P. CRANE. **Method of molding rubber reinforced with parallel fibers of steel wool.**

U. S., 1,153,040, Sept. 7. H. DEBAUGE. **Caoutchouc** is purified by attrition and heating in a solvent, e. g., xylene, and subjecting the soln. to dialysis to remove resins, S, etc.

Brit., 9,066, Apr. 9, 1914. R. C. FULTON and D. A. MACCALLUM. Coagulating latex from rubber and like trees, and curing it, by treatment with aldehydes or ketones other than HCHO in an inert carrier or diluent, such as H_2O , but excluding alc. *E. g.*, 80-90 parts of H_2O are added to 10-20 parts of aldehyde or ketone, and this dild. soln. may be used with about half its vol. of latex, which is preferably poured into or sprayed over the coagulant. Formalin to the extent of 1% may be added to the latex before coagulation.

Brit., 10,030, Apr. 23, 1914. H. GARE. Regenerating old vulcanized rubber in the manuf. of India rubber or ebonite goods by adding sufficient H_2O or other suitable inert fluid to the rubber during or after grinding to bring it to a semi-fluid or pasty condition, and then molding in this condition and pressing out the bulk of the H_2O , etc., prior to subjecting the rubber to the action of heat for vulcanization or reformation, *e. g.*, at 300°F . After the pressing operation, residual moisture may be evapd. with or without warming. Softening, hardening, bleaching, coloring, or like agents may be mixed with the rubber mass or added H_2O , etc.

Brit., 10,833, May 2, 1914. S. J. PRACHEY. Accelerating the vulcanization of natural or artificial caoutchouc-like substances, with the aid of *p*-nitrosodiphenylamine or reduction products of the nitroso compds. such as dimethyl-*p*-phenylenediamine, mentioned in the parent specification, 4,263, 1914 (*C. A.* 9, 2163).
